Re: 67 Sylvester Street Holdings LLC's Supplemental Response to EPA's Notice of Potential Liability and Request for Information for the New Cassel/Hicksville Ground Water Contamination Superfund Site

Dear Ms. Kivowitz:

In 67 Sylvester Street Holdings LLC's April 17, 2014 response to EPA's request for information under CERCLA § 104(e), we indicated that we had requested, under New York's Freedom of Information Law, records from the New York State Department of Conservation ("DEC") related to response activities for the Former LAKA Industries site at 62 Kinkel Street, Westbury, New York. On April 22, DEC fulfilled our request.

We therefore enclose the documents that DEC furnished as the following supplemental exhibits to 67 Sylvester Street Holdings LLC's CERCLA 104(e) response:

Exhibit M	Focused Remedial Investigation Report for the Former LAKA Industries Site, Volume I (Nov. 1998)
Exhibit N	Focused Remedial Investigation Report for the Former LAKA Industries Site, Volume II (Nov. 1998)
Exhibit O	Focused Remedial Investigation Report for the Former LAKA Industries Site, Volume III (Nov. 1998)
Exhibit P	Focused Remedial Investigation Report for the Former LAKA Industries Site, Volume IV (Nov. 1998)
Exhibit Q	Draft Final Vapor Intrusion Investigation Report, New Cassel Industrial Area Site # 130043 (May 2011)

Respectfully submitted,

Scott Furman

CHAPTER 1

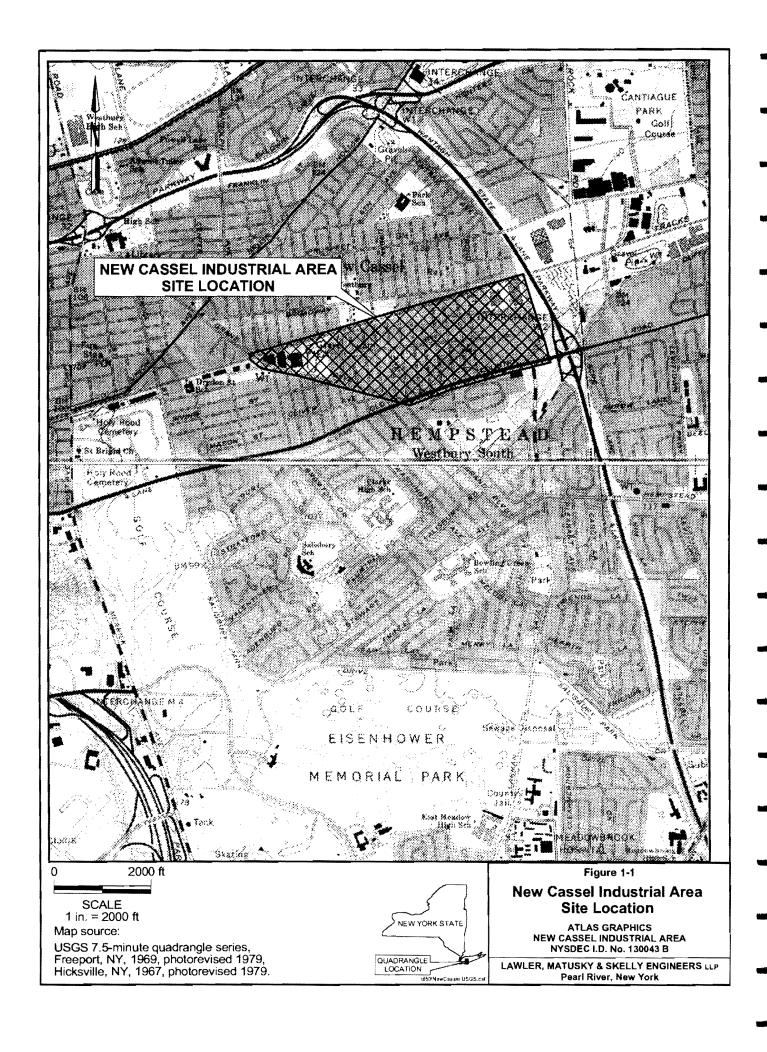

EXECUTIVE SUMMARY

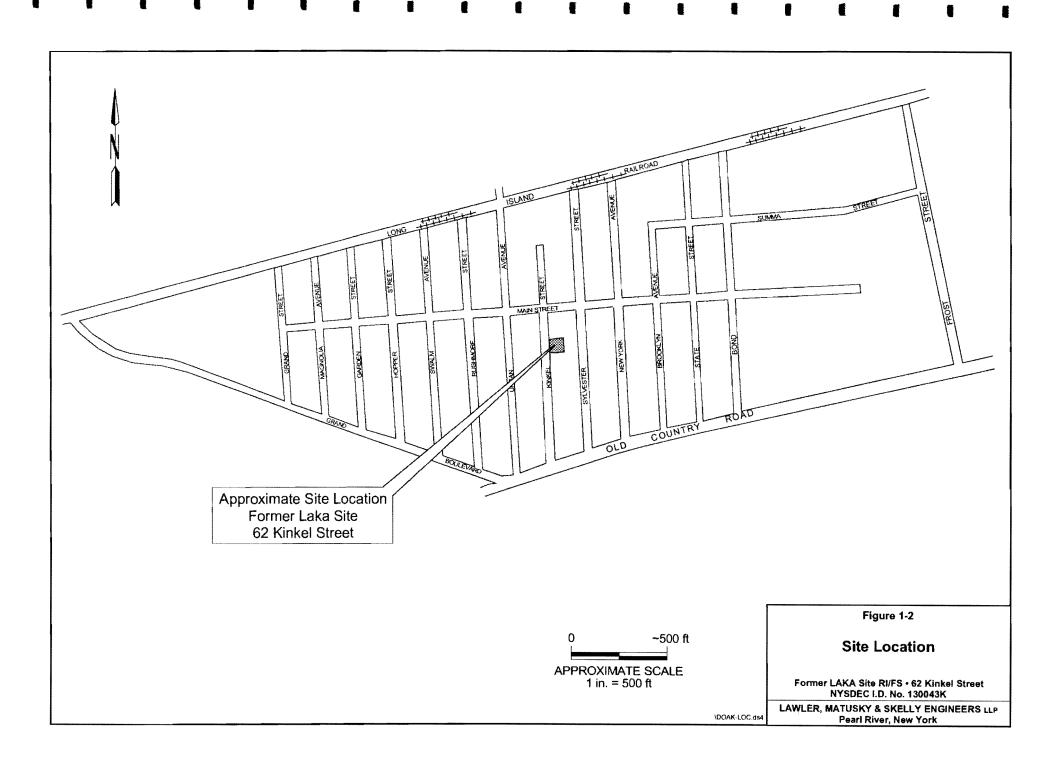

The former LAKA site (No. 1-30-043K on the registry) is located at 62 Kinkel Street in the New Cassel Industrial Area (NCIA) (Figure 1-1), Town of North Hempstead, Nassau County, New York (Figure 1-2). The site is comprised of approximately three quarters of an acre of land that is occupied by a pharmaceutical manufacturing company, Doak Pharmacal (Doak). The Doak building occupies the former LAKA site and extends beyond the property line to the Sylvester Street side of the block to the east (Figure 1-3). The site is entirely paved or covered with the footprint of the building with the exception of two small landscaped areas in front of the building (west side).

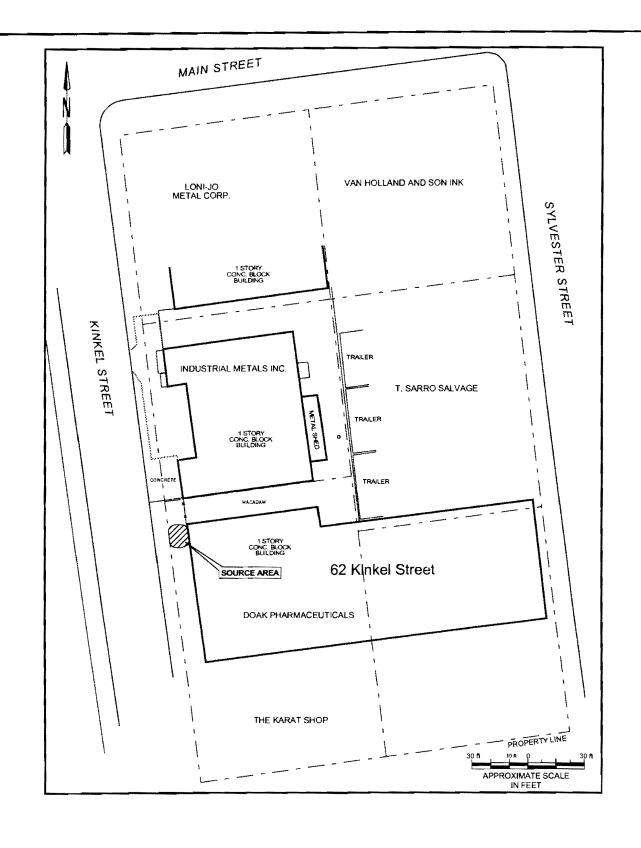

In 1986, extensive chlorinated solvent contamination (10-9,800 μ g/l) was discovered in the Upper Glacial Aquifer (UGA) and Magothy Aquifer, which underlie the NCIA and former LAKA site. During a NYSDEC PSA at the NCIA an abandoned leach pool was discovered off the northwest corner of the existing Doak building. Two samples collected from this area were heavily contaminated with chlorinated solvents. This site was included on the Registry of Inactive Hazardous Waste Disposal Site as a Class 2 site based on this on-site source and an apparent impact to the groundwater below the site.

From 1971 to 1978, the LAKA Tool and Stamping Co., Inc. occupied the site, performing precision metal stamping operations as a defense contractor. Operations primarily consisted of tool and die manufacturing. A Nassau County industrial chemical waste survey revealed 55 gallons of trichloroethylene (TCE) was used at the site each year, in conjunction with a vapor degreaser. Sludge from the vapor degreaser was reportedly placed in containers, however, its final disposal method is unknown. Additionally, 15 to 20 gallons of cutting oil was used annually during production. The site history for the former LAKA site indicates that the main contaminants of concern are VOC's and SVOC's. The VOC's are primarily halogenated volatile organic compounds used in degreasing while the SVOC's were used as lubricants or cutting oils.

NYSDEC assigned Lawler, Matusky & Skelly Engineers LLP (LMS) the task of conducting a Focused Remedial Investigation (FRI) to define the nature and extent of the on-site contamination. A work plan outlining the specific FRI tasks was approved by the NYSDEC and a notice to proceed was issued on 18 November 1997. This report presents the results from the FRI at the former LAKA site between January 1998 and September 1998.

-	ENVIRONMENTAL SCIENCE & ENGINEERING CONSULTANTS	Former LAKA Site RI/FS, 62 Kinkel Street NYSDEC I.D. No.: 13004	3K doaksit2.dsf

Topography at the former LAKA site is essentially level with an elevation of approximately 120-ft above mean sea level. There are no significant sources of surface water directly surrounding or in the immediate vicinity of the former LAKA site. Land use in the area is primarily industrial, commercial, and residential. Commercial property dominates along Old Country Road while land use north and south of the industrial area consists primarily of residential property. Based on an ecological communities classification system outlined by the New York State Department of Environmental Conservation the New Cassel Industrial Area is entirely comprised of a terrestrial cultural community. The climate of Long Island is moderated by its proximity to the ocean with an average annual temperature of 52.7° F and annual precipitation averaging about 44 inches per year (USGS, 1963).

Long Island regional hydrogeology consists of a significant thickness of unconsolidated sediments (Cretaceous and Pleistocene age) overlying Precambrian and Paleozoic basement bedrock. The bedrock surface is found at an average depth of approximately 1000-ft below sea level (USGS, 1989). Of primary concern for this investigation are the upper Pleistocene deposits and the underlying Magothy Formation. The upper Pleistocene deposits of poorly sorted sands and gravel that make up the upper glacial aquifer (UGA) are found from the surface to a depth of approximately 70-ft below the surface. The Magothy Formation consists of interbedded lenses and layers of fine to medium sand, clayey sand and solid clay with a basal, water-bearing, gravel zone. The Magothy is the major aquifer for public supply to nearly all of Long Island. The depth of the upper surface of the Magothy is found at about 70-ft below the surface. The UGA and Magothy are in direct hydraulic connection in the study area. Depth to water is about 50 to 55 ft below the ground surface in the study area and groundwater flows to the southwest. Hydraulic conductivity values for the UGA in the study area range from 58 to 391 ft/day. Hydraulic conductivity values based on slug tests conducted in deeper wells (Magothy Formation) were generally lower, ranging from 4 to 103 ft/day.

The field investigation activities for the FRI included two phases of soil probes. During the first phase 26 probe locations were sampled. Four additional probes were completed during the second phase of sampling. A total of 69 soil samples were obtained from the probes and submitted for TCL VOC's; in addition 21 of the soil samples were also submitted for TAL metals. The probe unit was also used to collect sediment samples from a drainage structure located at 54 Kinkel Street.

Analytical results from the FRI soil probes completed at the site indicate that acetone, xylene, trichloroethylene (TCE), and 2-butanone are present at levels exceeding the NYSDEC recommended soil cleanup objectives included in the November 1992 Technical and Administrative Guidance Memorandum (TAGM). Several metals were also found at levels exceeding the recommended cleanup objectives but it is believed the levels found are typical background levels

for this industrialized area. Based on the observations during the PSA and the FRI soil probes, it appears the former leachpool which was located off the northwest corner of the building was removed or cleaned when the existing building was connected to the county sewer system. The sampling results support this assumption in that only limited hot spots of contamination were found in the former pool location. The other soil probes which were installed across the site did not indicate that additional source areas are located in the areas that were sampled.

The existing drainage structure located in the parking lot at 54 Kinkel Street contains levels of VOC's and SVOC's which exceed the recommended cleanup objective for these compounds. The drainage structure also contains levels of metals including chromium and cadmium above the recommended cleanup objectives. It is not known if the presence of these contaminants are related to activities associated with the former LAKA operation. Based on the location of this drainage structure any runoff from the former LAKA site along the southern side of the building would be directed to the structure.

Probe groundwater samples collected in September 1998 from below the former leachpool revealed the presence of several compounds exceeding NYSDEC Class GA Standards. These samples were collected from three depth intervals: 62-63 feet, 72-73 feet, and 92-93 feet below ground surface. In the shallow interval, the concentration of tetrachloroethylene (PCE) (2 mg/l) was found to exceed NYSDEC Class GA groundwater standards. At the intermediate depth interval concentrations of 1,1-dichloroethylene (1,1-DCE), 1,1,1-trichloroethane (TCA), TCE, and PCE exceed NYSDEC Class GA groundwater standards. Concentrations of acetone, 1,1-dichloroethane (1,1-DCA), 1,2-DCE (total), 1,1,1-TCA, TCE, benzene, and PCE exceed standards in the deepest sampled interval.

A total of 7 monitoring wells (3 shallow wells and 4 deep wells) were installed during the FRI. Each of these wells and 6 existing wells were sampled and analyzed for TCL VOCs. The groundwater analytical results for the 13 monitoring wells showed concentrations of VOCs in excess of the Class GA groundwater standards in all wells sampled. Each well had various halogenated volatile organic compounds including 1,1,1-TCA, TCE, PCE, and the breakdown products of each compound. In the shallow wells total VOCs ranged from 14 µg/l to 26 µg/l in the two upgradient wells (MW-201 and FLMW-204A) to 215 µg/l in one of the downgradient wells (FLMW-206A). In the deep wells total VOCs ranged from 80 µg/l in the upgradient well to 340 µg/l in one of the downgradient wells (FLMW-205B). Based on the results of the groundwater sampling and analysis past activities at the former LAKA site have contributed to the known groundwater contamination in this area of the NCIA. The contamination has affected both the UGA and the upper zones of the Magothy Aquifer. The analytical results from the upgradient wells indicate that additional upgradient groundwater contamination has migrated onto the former LAKA site. The exact vertical and horizontal limits of the plume could not be determined due to the

presence of upgradient groundwater contamination.

Most of the property is paved and used for industrial purposes, hence exposure pathways to the contamination are limited. Currently, there are no on-site pathways of exposure to the groundwater since no private or municipal water supply wells exist on-site and the groundwater is not used in any other capacity. Off-site pathways within the NCIA are also not believed to exist based on the focused RI and previous investigations. The potential for downgradient exposure pathways through the groundwater are being addressed by other NYSDEC investigations due to the presence of multiple sources of contamination within the NCIA.

Remedial action objectives are developed for a site to determine the levels to which contaminant concentrations must be reduced to protect human health and environment. The remedial action levels for this site are based on established NYSDEC recommended soil cleanup objectives and NYSDEC Class GA groundwater standards for each of the contaminants of concern. Based on the limited amount of soils found in excess of the cleanup objectives approximately 22 cubic yards of contaminated soils are found near the former leachpool area. In addition to these soils another 4 cubic yards of contaminated sediments are found in the drainage structure located at 54 Kinkel Street.

CHAPTER 2

INTRODUCTION AND BACKGROUND

2.1 SITE LOCATION AND DESCRIPTION

The former LAKA site (No. 1-30-043K on the registry) is located at 62 Kinkel Street in the NCIA, Town of North Hempstead, Nassau County, New York (Figure 1-1). The site is comprised of approximately three quarters of an acre of land that is bounded by Kinkel Street to the west, Industrial Metals, Inc. to the north and The Karat Shop to the south (Figure 1-2). Doak Pharmacal (Doak) currently operates on the property formerly occupied by LAKA. The Doak building occupies the former LAKA site and extends beyond the property line to the Sylvester Street side of the block to the east (Figure 2-1). The site is entirely paved or covered with the footprint of the building with the exception of two small landscaped areas in front of the building (west side). During Preliminary Site Assessment (PSA) facility inspections, no floor drains were noted within the building however the building has been modified significantly for its current use. Currently the building uses the municipal water supply and the public sewer system. It is not known when the transition was made from using leachpools to the public sewer although it is believed this took place sometime in the early 1980's.

2.2 SITE BACKGROUND

The former LAKA site is located in the NCIA, which contains numerous Registry sites as a result of past disposal practices. In 1986, extensive chlorinated solvent contamination ($10-9,800~\mu g/l$) was discovered in the UGA and Magothy Aquifers, which underlie the site. Lawler, Matusky & Skelly Engineers LLP (LMS) conducted a PSA throughout the NCIA, during this Γ SA an abandoned leachpool was discovered off the northwest corner of the existing Doak building. Samples collected from this area were heavily contaminated with chlorinated solvents. This site was included on the Registry of Inactive Hazardous Waste Disposal Sites as a Class 2 site based on this on-site source and an apparent impact to the groundwater below the site.

From 1971 to 1978, the LAKA Tool and Stamping Co., Inc. occupied the site, performing precision metal stamping operations as a defense contractor. Operations primarily consisted of tool and die manufacturing. A Nassau County industrial chemical waste survey revealed 55 gallons of TCE were used at the site each year, in conjunction with a vapor degreaser. Sludge from the vapor degreaser was reportedly placed in containers, however, its final disposal method is unknown. Additionally, 15 to 20 gallons of cutting oil was used annually during production. Nassau County Department of Health (NCDOH) records indicate that wastes were evaporated, and there is no

documentation confirming discharge to a cesspool.

2.3 REPORT ORGANIZATION

The former LAKA Industries FRI is composed of Chapters 1 through 6. An executive summary of the FRI objectives, site history, and FRI findings are presented in Chapter 1. Chapter 2 outlines background information regarding the location, description and history of the former LAKA site. Procedures for field investigations can be found in Chapter 3, including details on soil probing and monitoring well installation, development, sampling and testing. Descriptions of the site geology, hydrogeology, climate and land use as well as other physical characteristics of the site can be found in Chapter 4. Chapter 5 presents the nature and extent of contamination from the findings of previous investigations and from this FRI. A summary of the FRI findings, interpretation of the data and objectives for remedial action are found in Chapter 6.

Data and field logs are arranged in appendices at the end of the report. Appendix A consists of sampling logs from soil and groundwater probing at the site. Appendix B contains monitoring well boring and installation logs. Appendix C contains logs from the development of the monitoring wells on and surrounding the site. Results from performing in-situ hydraulic tests using the new and existing wells are compiled in Appendix D. Appendix E consists of groundwater sampling logs recorded during the sampling of both the new and existing monitoring wells. Data validation and usability reports are contained in Appendix F. Analytical data summary sheets from monitoring well groundwater samples are found in Appendix G. Appendix H contains the analytical data summary sheets from the probe samples collected at the site.

CHAPTER 3

FIELD INVESTIGATION PROCEDURES

3.1 INTRODUCTION

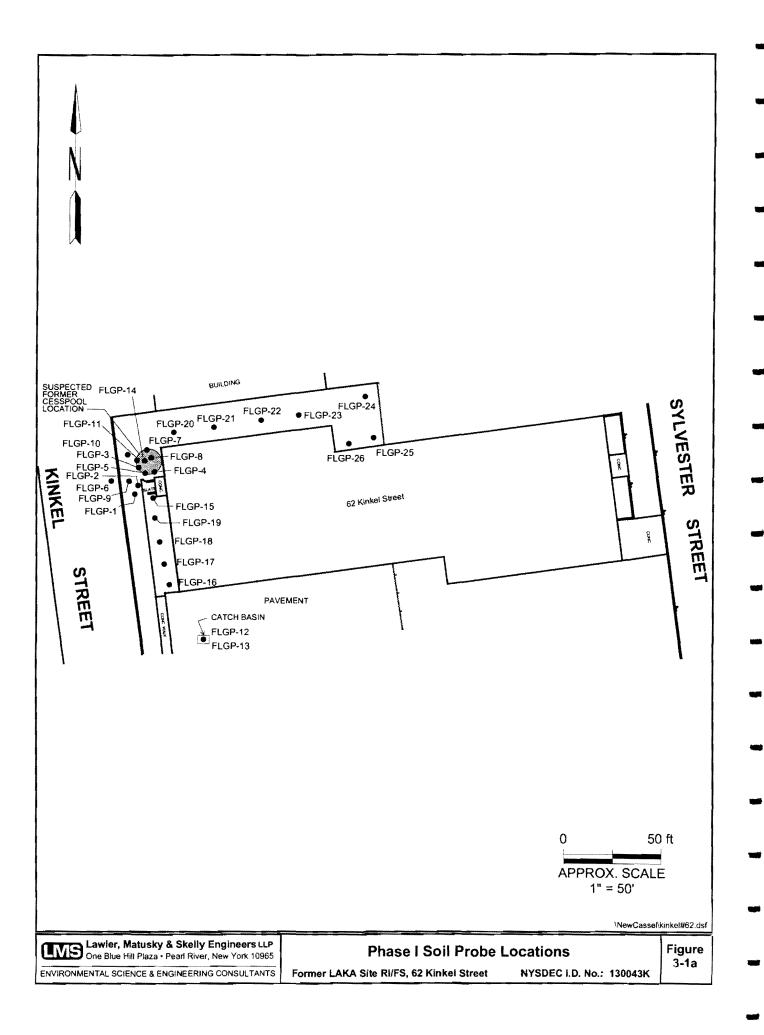

Field investigations at the former LAKA site were conducted to further delineate the extent of source area contamination and to provide improved monitoring of groundwater quality at the site. Lateral and vertical delineation of subsurface soil contamination was determined through laboratory analysis of probe samples and on-site monitoring of split spoon samples collected during the installation of monitoring wells. Pairs of new monitoring wells consisting of a shallow and a deep well were installed upgradient and downgradient of the site and sampled to determine the extent and magnitude of groundwater contamination resulting from past practices at the site.

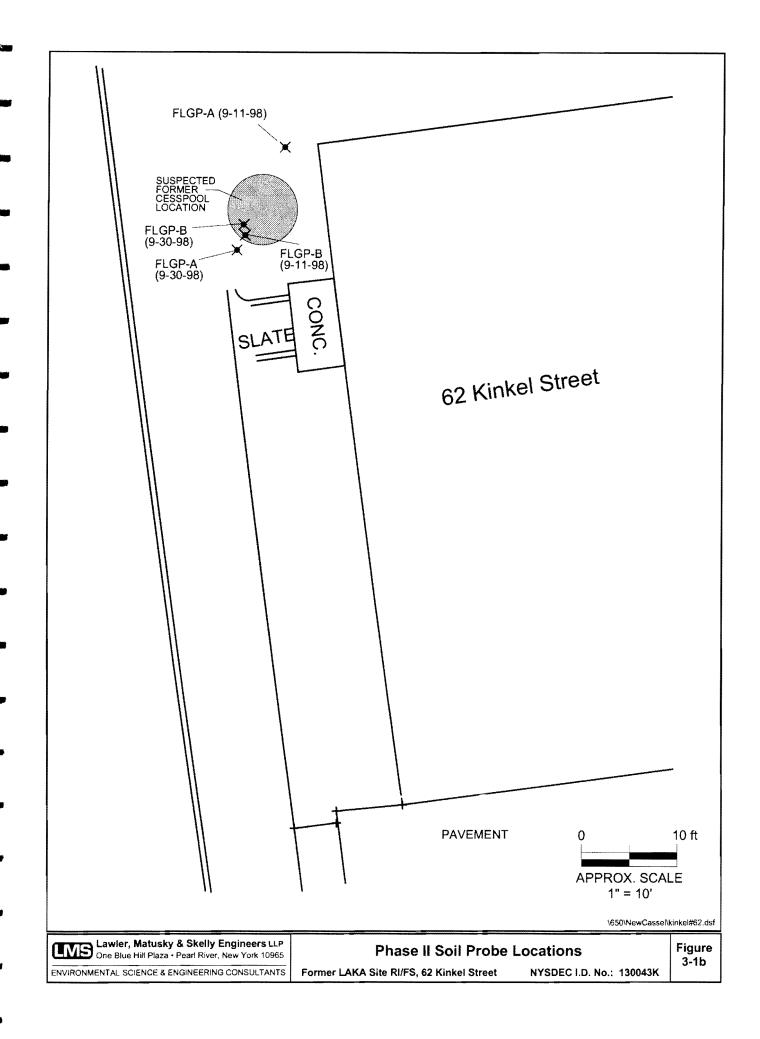

3.2 PROBE SAMPLING

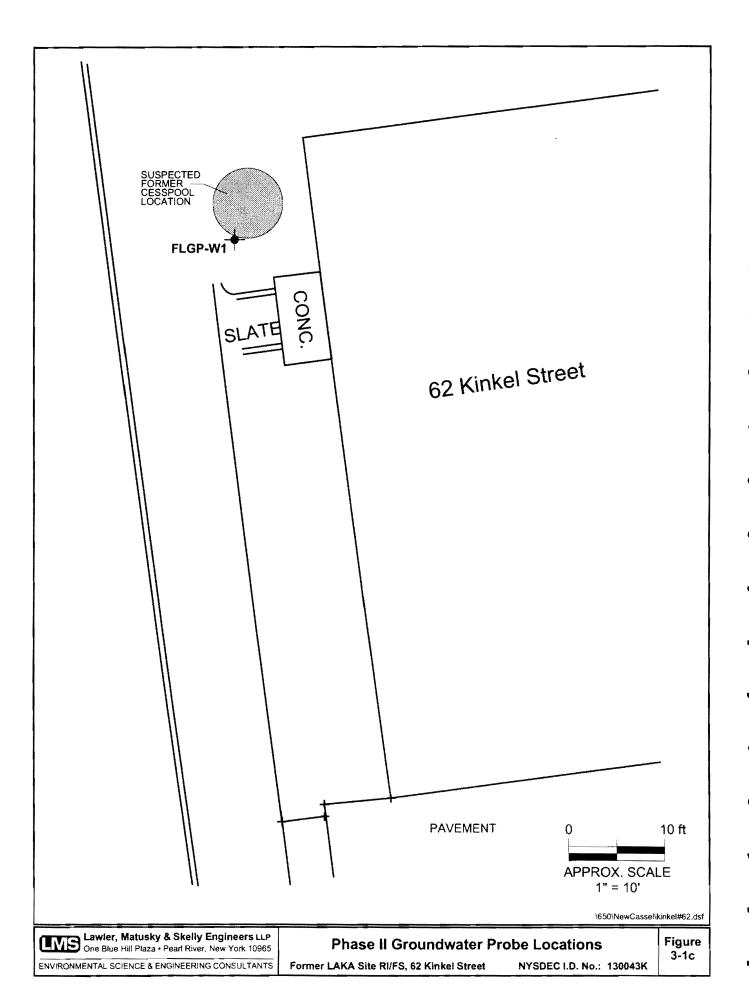

3.2.1 Phase I Soil Probes

A total of 24 probe borings, advanced by a truck mounted probe unit, were completed along the north and west sides of the Doak building (Figure 3-1a). The probe unit was operated by Vironex of New Jersey. Continuous probing to 24 ft bgs was performed at 17 points between the west face of the building and Kinkel Street. This was done to assess the extent of contamination surrounding the known source area at the northwest corner of the Doak building and to search for sources along the edge of the building south of the known source. Advancement of five of these probes continued to greater depths in an attempt to sample groundwater near the top of the water table. However, due to shallow refusals groundwater probe samples were not collected during the first phase of the probing. In the alley north of the building 7 borings were advanced to 24 ft bgs to address the possibility of additional source areas. Two additional borings were done by hand through a drainage grate in the parking lot of 54 Kinkel Street (south of the Doak building) to collect sludge samples.

Samples were collected in 4 ft runs using a 1.5-in. inside diameter (I.D.) macro core sampler. Generally this sampler is only useful to depths of approximately 16 feet due to the likelihood of hole collapse. During the course of this investigation however, the macro core sampler was often used to depths of 24 ft bgs without significant problems. At depths greater than 24 ft bgs or if hole collapse did become a problem, the large bore sampler was utilized. This sampler is smaller in diameter (1.0 in. I.D.) and collects material in 2 ft runs. Soil recovery was accomplished in the same manner for both samplers. Dedicated acetate liners were placed inside the steel sampler

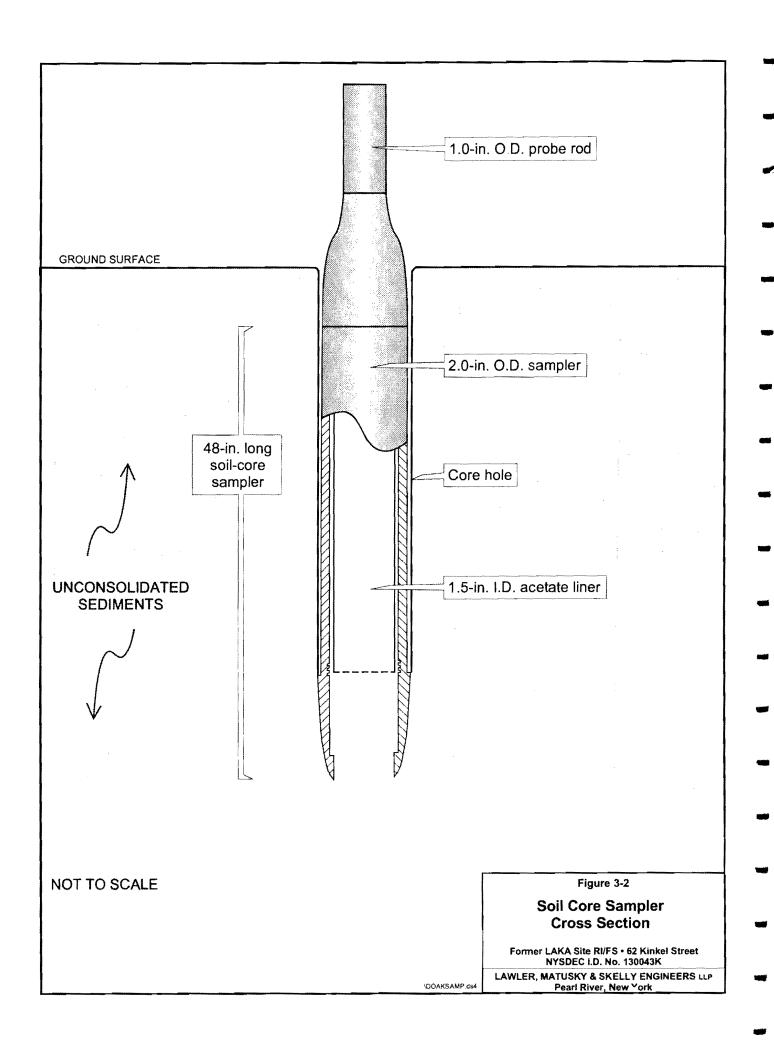

before the sampler was advanced to the desired depth using the hydraulic driven probe system (Figure 3-2). Upon removal from the sampler, soil contained within the liner was scanned with a flame ionization detector (FID) or photo ionization detector (PID) for the presence of volatile organic compounds (VOCs). Based on the results of this on-site scanning, portions of the recovered soil were transferred to laboratory-cleaned glass jars for VOC analysis. Typically, portions of the recovered material showing the highest response above background levels when scanned with the PID or FID would be submitted for VOC analysis. In borings where no significant VOC levels were detected by the PID or FID samples were collected from near the surface (0 to 4 ft bgs), near the bottom of the boring (20 to 24 ft bgs) and, in some cases, mid-boring (12 ft bgs). Samples were also collected for TAL metals and CN analysis. These samples were collected as composite samples from a portion of the core of soil recovered in the acetate liners. Therefore, the TAL metals and CN samples were not necessarily correlated to high VOC content as detected by the PID or FID. All soil samples submitted for analysis to Accredited Labs were labeled with sample location, interval, date, time, sampler and required analysis. The samples were then logged on a chain of custody record, securely packaged in ice and shipped overnight via Federal Express to Accredited Laboratories for analysis.

3.2.2 Phase II Soil and Groundwater Probes

In September 1998 four additional soil probes from the source area and a probe to collect groundwater from below the source area were completed. Figure 3-1b is a plan view of source area at 62 Kinkel Street and the location of the additional soil probes. Figure 3-1c shows the location of the groundwater probe point.

The additional soil probes were completed following procedures used for previous soil probes at the site using an AMS truck mounted probe owned by LMS. Since the purpose of the additional soil probes was to characterize the level of contamination in a sludge layer at approximately 16 feet below the surface, three of the probes were advanced to 24 feet bgs and the fourth probe was completed to 28 feet bgs. A total of only two samples were submitted for analysis from the material recovered from these four probes. The samples that were submitted were from material exhibiting the highest PID readings. Each sample was collected in a laboratory-cleaned glass container and submitted for VOC analysis. Sample logging, packaging, and shipment followed the procedure outlined above in the description for the Phase I soil probes.

One soil sample was collected and shipped to the analytical laboratory on 11 September 1998. Since it was anticipated that further sampling would take place, no MS/MSD samples were submitted with this sample.

Due to delivery/receiving problems at the analytical laboratory sampling was repeated on 30 September 1998 at a different soil probe located several inches from the original. Containers with soil samples from this probe were submitted for VOC and MS/MSD analysis in accordance with the procedures detailed above.

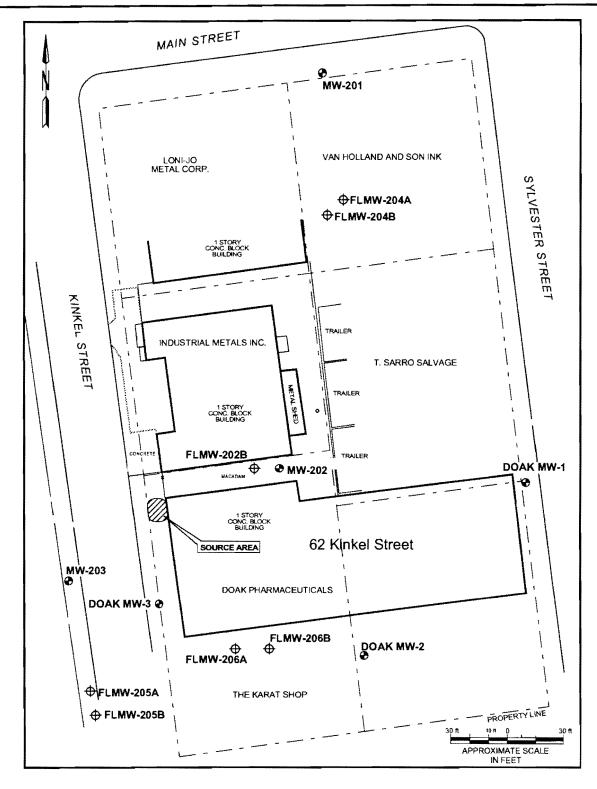

In addition to the soil probes, the AMS probe was used to advance probe rods fitted with a disposable tip and sediment screen for groundwater sampling at discrete intervals. In this method the probe rods are driven approximately two feet below the depth of the deepest desired sampling interval. The rods are then pulled up to the sampling interval, with friction pulling off the disposable tip. This then leaves the bottom rod open and allows groundwater to enter the rod. At the very end of the bottom rod is a fine screen designed to allow the entrance of water but not sediment in to the rod. If water is detected in the rods, the volume of the water column is calculated and three volumes are purged from the rods before sampling. Dedicated tubing is used for hand purging and sampling at each interval. After the sample is collected the rods are pulled up to the next deepest sampling interval and the purging and sampling process is repeated.

3.3 MONITORING WELL INSTALLATION

3.3.1 General Monitoring Well Details

Seven new monitoring wells were installed surrounding the former LAKA site from 14 to 29 January 1998. Three wells were placed upgradient and four downgradient of the known source area at the former LAKA site (Figure 3-3). Pairs of shallow and deep wells were drilled in close proximity in order to provide data on groundwater quality at different levels within the aquifer(s). The shallow wells were set in the UGA at depths of approximately 60 ft bgs while the deep wells were screened in the upper portion of the Magothy Aquifer at about 110 ft bgs. The deep wells were originally to have been set at the bottom of the UGA, however, based on our interpretation of the split spoon samples it appears that the UGA-Magothy interface is found significantly shallower than anticipated. Figures 3-4a and b show geologic cross-sections A-A' and B-B' which run approximately north-south and east-west through the site, respectively. Although there was a noticeable change in the transition from the UGA to the Magothy, no significant confining layer was encountered that would preclude downward migration of contaminants. Based on this information, it was decided that the deep wells would be set at 110 ft bgs in order to provide some indication of the water quality in the upper Magothy Aquifer.

All of the newly installed wells were drilled using a 4.25-in. I.D. hollow stem auger, as shown in Figure 3-5, and constructed from ten foot sections of threaded, flush-joint 2-in. Schedule 40 PVC (Figure 3-6). Each of the new wells was fitted with 10 feet of 10-slot sized PVC screen. The sand

ENVIRONMENTAL SCIENCE & ENGINEERING CONSULTANTS

filter pack surrounding the screened interval of each well consisted of No. 1 grade Morie sand installed to a minimum of 2 ft above the top of the screen. The well seal was installed above the sand pack. In deep wells the seal consisted of thick bentonite slurry since it was installed below the water table. Because the seal was above the water table in the shallow wells, a layer of bentonite pellets at least 2-ft thick was added to the annulus of the well and hydrated with water pumped down the borehole. After installing the sand pack and bentonite seal the remaining volume of the borehole was filled to just below the surface with a bentonite and cement grout. The remainder of the borehole was filled with clean sand to provide adequate drainage around the protective case. Finally, a flush mounted well cover was installed with a surrounding cement pad. All cuttings from the drilling of the wells were containerized in a 15 cubic yard hazardous waste rolloff located next to the west face of the Doak building. Installation details for each well can be found in the field well logs in Appendix B.

3.3.2 Monitoring Well Soil Sampling

During installation of each of the deep wells ('B' designation) soil samples were collected using a 1.375-in I.D. split spoon sampler (Figure 3-5). The sampler was driven with either a 140-lb or 175lb hammer in accordance with the standard penetration test method ASTM-D 1586. Sampling was not conducted during the drilling of the shallow wells ('A' designation) due to the close proximity to their deep counterparts. Samples were collected in 2-ft runs at 5-ft intervals from the ground surface to the bottom of the well boring. Upon recovery of the split spoon sample the soil was immediately scanned for VOCs using an FID or PID and the reading (relative to background), sample interval, soil description, blow counts, moisture content, color and evidence of contamination entered on a test boring log. Field boring logs completed during installation of the wells are contained in Appendix B. Portions of each sample were bagged and labeled for field reference and comparison purposes while drilling the remaining wells but no split spoon samples were sent off-site for chemical analysis. During installation of FLMW-202B, split spoon sampling was not initiated until reaching 60-ft bgs since logging of the soil to 60-ft had been done by ABB Environmental Services during their installation of MW-202 (FLMW-202B was installed as the deep counterpart of MW-202). In some cases the samples were taken at 10-ft intervals to expedite the installation if the LMS geologist judged the characteristics of the soil remain constant over a significant thickness.

3.3.3 Specific Monitoring Well Details

FLMW-202B This well, located in the alley north of the Doak building (Figure 3-3), was the first of the new wells drilled and installed. FLMW-202B is the deep counterpart to a pre-existing shallow well approximately five feet to the east. All deep wells were originally specified to be

completed to a depth of 110 ft bgs or at the bottom of the UGA. Due to difficulties in discerning the UGA-Magothy interface based on the split spoon samples it was decided that this boring would be advanced deeper than originally planned in an attempt to find a significant change in stratigraphy (i.e. confining layer). At 122 ft bgs drilling was halted since no confining layer was found. Delta Well and Pump drilled this well using a 4.25-in I.D. hollow stem auger over the course of three days from 14 to 16 January 1998. As described above, split spoon samples were not taken for the first 60 ft bgs during the drilling of this well. The well was set at 121 ft bgs with a screened interval from 111 to 121 ft bgs. The sand pack, bentonite slurry and grout were all installed according to NYSDEC specifications and a flush mount protective case and concrete pad with a slight rise for drainage was installed surrounding the well cover.

FLMW-206B This well was installed by Delta Well and Pump between 19 to 21 January 1998 at the north edge of the parking lot located at 54 Kinkel Street, just off the south face of the Doak building (Figure 3-3). Split spoon sampling was conducted from the surface to a depth of 110 ft bgs at 5-ft intervals. Total depth of the well is 111 ft bgs with a screened interval of 100 to 110 ft bgs. The filter pack, bentonite slurry and grout were installed in accordance with NYSDEC specifications. A flush mount protective case and concrete pad with a slight rise to insure proper drainage was installed surrounding the well cover.

FLMW-206A The shallow counterpart to FLMW-206B, FLMW-206A was drilled and installed by Delta Well and Pump on 21 January 1998 approximately 10 ft west of FLMW-206B (Figure 3-3). The well was set just short of 60-ft bgs with a static water level measured at 53.1 ft bgs. The screened interval for the well is 50 to 60 ft bgs. The filter pack and grout were installed according to NYSDEC guidelines. Bentonite pellets were added instead of bentonite slurry since the bentonite seal was above the water table. The bentonite pellets were allowed time to adequately hydrate before grouting the hole to the surface. A flush mounted protective case was then installed over the riser with a slightly raised concrete pad to insure good drainage.

FLMW-204A This well was installed as a shallow well upgradient from the former LAKA site. Delta Well and Pump drilled and installed FLMW-204A on 22 January 1998 in an alley west of 71 Sylvester Street (Figure 3-3). The alley was filled with scrap metal and pieces of metal duct work as well as pallets full of salvaged computer equipment (monitors, printers and CPUs). The amount of material in the alley made it necessary to shift the location of FLMW-204A/B further north in the alley than originally planned. Further complicating drilling in this alley was the presence of 1/8-in-thick steel plates buried as deep as one foot below the gravel at the surface. Several attempts were made at drilling in this location before the auger finally penetrated into natural material. The well, when completed, was set just over 60-ft bgs and screened from 50 to 60-ft bgs. The filter pack, bentonite pellets and grout were installed in accordance with NYSDEC guidelines. Due to the

amount of gravel at the surface it was decided that a slightly raised concrete pad surrounding the protective case would not be necessary for drainage. A small ring of concrete was poured and the protective case was inserted such that the cover was just above the level of the gravel. When the concrete set, displaced gravel was used to fill in the area around the cover so that it would be flush with the gravel and would not interfere with movement in the busy alleyway.

FLMW-204B Delta Well and Pump drilled and installed this deep well from 23 to 27 January 1998 approximately 20 ft southwest of FLMW-204A in the alley west of 71 Sylvester Street (Figure 3-3). Problems drilling around scrap metal buried by the surficial gravels were again encountered. Upon completion of drilling the well was set at a depth of 109.5-ft bgs with a screened interval over the final 10 ft. Filter pack sand, bentonite slurry and grout were all installed according to NYSDEC guidelines. Installation of the well cover was identical to that done for FLMW-204A.

FLMW-205A The final pair of wells installed for this phase of the investigation was completed in the right of way on the west side of Kinkel Street across from 54 Kinkel Street (Figure 3-3). The shallow well of the pair, FLMW-205A, was installed first by Delta Well and Pump from 27 to 29 January 1998. This boring was completed to a depth of 61 ft bgs and the well was set at 60.6 ft bgs and screened from the interval 50 to 60 ft bgs. The filter pack, bentonite pellets and grout were installed in the borehole to NYSDEC specifications. A flush mount protective case in a concrete pad was then installed over the PVC riser.

FLMW-205B As shown in Figure 3-3, this well was completed about 6 ft south of FLMW-205A by Delta Well and Pump on 29 January 1998. As drilling of the well proceeded, split spoon samples were collected at 5 ft intervals (10 ft intervals in some sections). FLMW-205B was drilled to a depth of 112 ft bgs and set at 110.9 ft bgs. The bottom 10 ft of the well consisted of 10-slot screen with filter pack sand added to six feet above the top of the screen. Bentonite slurry and cement/bentonite grout was added to the borehole as specified by NYSDEC guidelines. To protect the PVC riser, a concrete pad (with sloping sides for drainage) with flush mounted protective case was placed over the riser.

All seven of the newly installed wells were developed after installation. The new wells were allowed to set at least 24-hrs before development. In addition, six pre-existing monitoring wells (Figure 3-3) surrounding the former LAKA site were redeveloped in preparation for groundwater sampling. Well development logs detailing the development of all wells are contained in Appendix C. All development was done using a 2-in. submersible pump. The development water was pumped into a 250-gal holding tank before being discharged into a Nassau County sewer line. LMS was issued a permit by Nassau County to discharge development and purge water into two sewer manholes in the NCIA, at the intersection of Frost Street and Summa Avenue. Well development

commenced on 26 January 1998 and ended on 30 January 1998. The static water level was measured in each well prior to and after development. In addition, groundwater parameters such as pH, specific conductivity, temperature and turbidity were measured and logged during development. The older wells were redeveloped by pumping at a flow rate of approximately 2-gal/min for one hour and surging the well by rapidly starting and stopping the pump and by pumping at different levels within the water column. For all of the older wells this amount of pumping was enough to clear the water to very low turbidity values (< 3.0 NTUs). Development of the seven new wells was done until the well had been pumped for two hours or the turbidity measured less than 5.0 NTUs. All seven new wells were developed at a rate of 2.5-gal/min for two hours since surging and movement of the pump through the water column resulted in rapid alternation between relatively clear and turbid water being pumped to the surface. In all but one well the effect of pumping on the static water level was minimal with virtually instantaneous recovery noted when the ending water level was measured. Only in DOAK MW-2 was appreciable drawdown of the water column observed after development (almost 3-ft). However, the water level returned to that measured before development in approximately 10 minutes.

3.3.4 In-situ Hydraulic Testing

Slug tests were performed on each of the wells after sampling was collected to characterize the hydraulic conductivity of the aquifers in which the new monitoring wells were screened. The slug test relates the response of the aquifer to an artificial change in water level at the monitoring well over time. A pressure transducer was first lowered into the water column in the monitoring well to a level well below that of the static water level and carefully fixed at that level to prohibit any movement. The transducer and water level were allowed to equilibrate and a stainless steel slug was lowered into the well to a point just above the top of the water column. At that point the static water level was set to be the reference level for the transducer. From this point any fluctuation in water level was displayed as a positive or negative displacement relative to the reference water level. The slug was then lowered instantaneously into the water, displacing an equal volume of water and raising the water level. At the moment the slug was lowered the Hermit data logger was activated to record the change in water level detected by the pressure transducer through time. The Hermit logger coupled with the transducer made it possible to record a large number of water level measurements in a short period of time. This was especially important in the wells tested here since the UGA and Magothy Aquifers are highly permeable and exhibit very rapid recovery after being stressed. The Hermit logger was set to collect data on a logarithmic time scale such that many measurements were taken early in the test and the frequency of measurement would decrease with time. Once it was apparent that the water level had fully recovered (approximately 10 minutes) the data logger was stopped and programmed for the next phase of the test that involved the removal of the slug from the water column. The data logger was started and the slug was quickly pulled out of the water and the recovery response was again logged for about 10 minutes.

Data from the slug tests were downloaded from the Hermit logger to a PC and used in AQTESOLV, a hydraulic testing analysis program. AQTESOLV utilized the Bouwer-Rice method and a graphical solver to calculate the hydraulic conductivity of the aquifer based on the data collected in the field. Appendix D contains the graphical presentation of the in-situ hydraulic testing data and results from analysis of these data.

3.4 GROUNDWATER SAMPLING AND ANALYSIS

3.4.1 Groundwater Sampling Protocol

Groundwater sampling was conducted at the thirteen wells surrounding the LAKA site shown in Figure 3-7. Six wells were installed during previous investigations. All of these pre-existing wells are shallow with a maximum depth of 68 ft bgs. The remaining seven wells were installed for this investigation. Appendix E contains the field groundwater sampling logs completed during well sampling conducted 9 to 12 February 1998.

Prior to sampling, each well was purged to remove water inside the well. A minimum of three well volumes was removed to insure that water being sampled was representative of that contained in the aquifer. Purging of shallow wells with water column heights less than ten feet was done by hand bailing due to the small amount of purging necessary. The pre-existing shallow wells often had larger water columns requiring prohibitive lengths of time to hand bail the required amounts of water. These wells and all deep wells were purged using a 2" Grundfos submersible pump. During purging of the wells, pH, conductivity, temperature and turbidity were monitored at intervals determined by the amount of water necessary for adequate purging. All purge water was containerized in a 55-gal drum for transport to a pre-determined Nassau County sanitary sewer manhole where it was disposed of using an electric drum pump.

Groundwater samples were collected after purging using dedicated Teflon bailers. At each well three 40 mL pre-cleaned glass vials were filled for TCL VOC samples and two 950 mL plastic containers were filled, one for TAL metals and the other for CN analysis. Sampling parameters (pH, conductivity, temperature and turbidity) were measured and recorded on a sampling log at the beginning and end of sampling at each well. QA/QC samples, including field blanks, matrix spike and matrix spike duplicate, and a blind duplicate, were also collected. Upon collection of samples they were immediately packaged in protective wrap and placed in a secure, ice-filled cooler for storage in the field. At the end of each day all samples were logged on an appropriate chain of custody record and carefully packaged on ice for overnight shipment to Accredited Laboratories.

CHAPTER 4

PHYSICAL CHARACTERISTICS

4.1 TOPOGRAPHY

The land surface at the former Laka site is essentially level with an elevation of approximately 120 ft above mean sea level. The land in this area naturally has only a very gentle southward slope and the flatness has likely been enhanced in the area surrounding the site by grading done during construction of the large number of surrounding buildings.

4.2 SURFACE WATER

Due to the density of commercial property and industrial buildings, there are no significant sources of surface water directly surrounding the former LAKA site. Virtually every open space in the industrial area has been covered by asphalt, concrete, or buildings. The nearest sources are several small ponds in and around Eisenhower Memorial Park, approximately two miles southwest of the site across Old Country Road.

4.3 DEMOGRAPHY AND LAND USE

The former LAKA site is located in the town of North Hempstead (Nassau County, New York). Based on the 1990 census the population of the county is 1.3 million and of North Hempstead about 200,000 (U.S. Department of Commerce, 1990). The New Cassel Industrial Area (NCIA) is a heavily industrialized area of a variety of small to medium sized businesses covering about 25 blocks. The NCIA is bounded to the north by the Long Island Railroad, to the south by Old Country Road, to the east by the Wantagh Parkway and to the west by Grand Boulevard. For miles east and west of the NCIA, along Old Country Road, commercial property dominates while land use north and south of the area consists primarily of residential property.

4.4 ECOLOGY

Based on an ecological communities classification system outlined by NYSDEC the NCIA is entirely comprised of a terrestrial cultural community. The terrestrial cultural subsystem is defined by communities that are direct results of the influence of human activities or are modified to such an extent as to be significantly changed from the community as it was before alteration by humans (NYSDEC, 1990).

From the classification system utilized by the NYSDEC, five ecological communities dominate the The first community (NYSDEC terrestrial cultural community #16) accounts for NCIA. approximately 20% of the NCIA and is characterized by roads and paths paved with asphalt, concrete, brick and stone with only sparse vegetation present in cracks in the surface. Junkyards (NYSDEC terrestrial cultural community #30) that have been utilized for storage of refuse are another component of the NCIA ecology and account for approximately 10% of the NCIA. Urban vacant lots (NYSDEC terrestrial cultural community # 31) comprise about 10% of the NCIA. These lots are characterized by debris laden, sparsely vegetated open sites within a developed area where construction is pending or demolition has occurred. Urban structure exteriors (community #32) and interiors of non-agricultural buildings (community #35) compose the majority of the NCIA. Approximately 35% of the area is made up of the interior of non-agricultural buildings, including those used for commercial or industrial purposes. Urban structure exteriors make up approximately 25% of the area of the NCIA and include exteriors of commercial buildings or any inorganic structural surface. Typically, only sparse vegetation is present but birds and insects are common. (NYSDEC, 1990)

4.5 CLIMATOLOGY

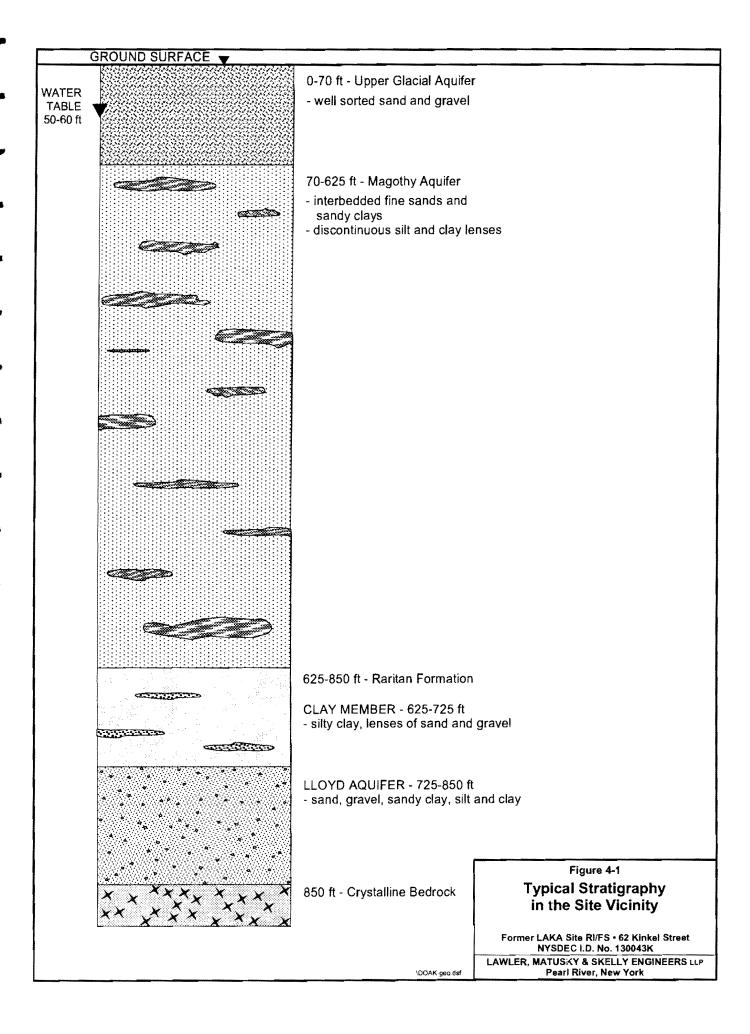

The climate of Long Island is moderated by its proximity to the ocean and land surfaces that are very close to sea level. Precipitation, distributed evenly through the year, averages about 44-in. per year with a range between approximately 32 and 58-in. per year. Rainfall amounts reach a maximum in August with 3 to 4.5 inches recorded in a typical year. Temperatures range from an average low of 32°F in January to an average high of about 75°F in July. The average annual temperature on Long Island over an 85 year period is 52.7°F (USGS, 1963).

4.6 GEOLOGY

4.6.1 Regional Geology

Long Island regional geology consists of a significant thickness of unconsolidated sediments (Cretaceous and Pleistocene age) overlying Precambrian and Paleozoic basement bedrock consisting of gneiss, schist and granite that forms the base of Long Island (Figure 4-1). The bedrock surface is found at an average depth of approximately 1000-ft below sea level and dips southward to the south shore of the island (USGS, 1989).

Directly above the bedrock lies the Raritan Formation, composed of the lower Lloyd Sand Member and an upper confining layer of clay. The Lloyd Sand Member is one of three important aquifers in the study area and consists of poorly sorted quartzose sands and gravel. The top of the Raritan

Formation is encountered at an average depth of approximately 400-ft below sea level with a maximum thickness of about 700-ft (USGS, 1989).

Unconformably overlying the Raritan Formation is the Magothy Formation, consisting of interbedded lenses and layers of fine to medium sand, clayer sand and solid clay with a basal gravel zone. The Magothy is the major aquifer for public supply to nearly all of Long Island. The depth of the upper surface of the Magothy is found at about 100-ft below sea level and the formation thickens to the south, reaching a maximum thickness of 1100-ft in some locations.

What lies above the Magothy Formation is a function of the geographical location on the island. In eastern Nassau County and Suffolk County the Monmouth greensand, a glauconitic greenish-grey to greenish black sand, silt and clay overlies the Magothy. This member acts as an upper confining unit for the Magothy, however, it has a very limited areal extent, pinching out about three miles inland from the south shore and disappearing altogether at the far eastern end of the island. Further west, in Kings and Queens counties, the Jameco Gravel, a mix of poorly sorted sands and small gravel, can be found in a layer approximately 100-ft thick extending from the south shore to the middle of the island (USGS, 1989).

The Gardiners Clay is another confining unit for the Magothy Formation or Jameco Gravel (if present) but it also has a relatively small areal extent. The occurence of the Gardiners Clay is limited to the south shore of the island, pinching out 5 to 10 miles inland from the shore. As the name implies, the Gardiners is characterized by greyish-green, glauconitic, silty clay with a maximum thickness of approximately 150-ft (more typically about 50-ft) (USGS, 1989).

Above the Gardiners Clay or the Magothy (where the Gardiners is absent) are upper Pleistocene deposits of clay, sand, gravel and boulders commonly referred to as the UGA (upper glacial aquifer). These deposits are composed of glacial till (morainal materials to the north and outwash deposits to the south) and constitute another important water source for the island (Buxton and Modica, 1992).

4.6.2 Study Area Geology

The geology underlying the former LAKA site in east-central Nassau County is somewhat simpler than the regional geology detailed above. The upper Pleistocene deposits of poorly sorted sands and gravel that make up the UGA are found from the surface to a depth of approximately 70-ft below the surface. The site is located far enough north and east in Nassau County such that the Gardiners Clay, Jameco Gravel and Monmouth greensand are all absent between the UGA and the underlying Magothy Formation. In general, the upper surface of the Magothy Formation is found at

least 100-ft below ground surface (USGS, 1989). However, based on observations made during installation of wells for this investigation and on published cross sections of the area (USGS, 1989), the Magothy is found at significantly shallower depths (70-ft bgs) in the Westbury (New Cassel) area than in many other areas of the island.

The nature of the materials collected in split spoons during installation of FLMW-202B, -204B, -205B and -206B were relatively consistent. As noted earlier, no samples were collected from FLMW-202B until a depth of 60-ft bgs was reached. However, it was noted that cuttings were typical of UGA material; orange-brown poorly sorted sands and quartz gravel. Beginning at a depth of 70-ft bgs, the material from FLMW-202B split spoons became significantly finer and displayed a variety of colors. This was interpreted as the transition from the UGA to the Magothy aquifers. Very fine sand and silt became common in these samples and stringers of grey clay began to appear. Between 80 and 105-ft bgs, multicolored (red, grey, purple, orange and brown) layers of silt and very fine to fine sand dominated the stratigraphy. From 110-ft bgs to the bottom of the borehole at approximately 120-ft bgs the multicolored banding of material became less prominent and iron staining and cementation of grains was observed in each sample. For the most part, silt, fine sand and clay comprised the majority of the material in this interval.

Split spoon samples taken during the drilling of FLMW-204B, -205B and -206B exhibit a transition between the UGA and the Magothy similar to that seen in FLMW-202B. In FLMW-205B the transition was noted at approximately 60-ft bgs. The top of the Magothy appeared even shallower, approximately 45-ft bgs, in FLMW-206B. Poor sample recovery was encountered due to problems with running sands in FLMW-204B. Because of this, it was difficult to determine where the transition between the UGA and the Magothy occurred. Based on the samples that were recovered the contact between the two aquifers is between 60 and 80-ft bgs.

4.7 SOILS

The soils in the area around the former LAKA site are medium - coarse grained, well drained soils of the Haven Variant association. This association is typically a deep soil formed on the nearly level land (0-3%) of the southern outwash plain. At depths between 20 to 36 inches the loamy, upper soils are underlain by stratified sands and gravel. The upper soil material is moderately permeable while the deeper sand and gravel has a very high permeability (USSCS, 1976).

4.8 HYDROGEOLOGY

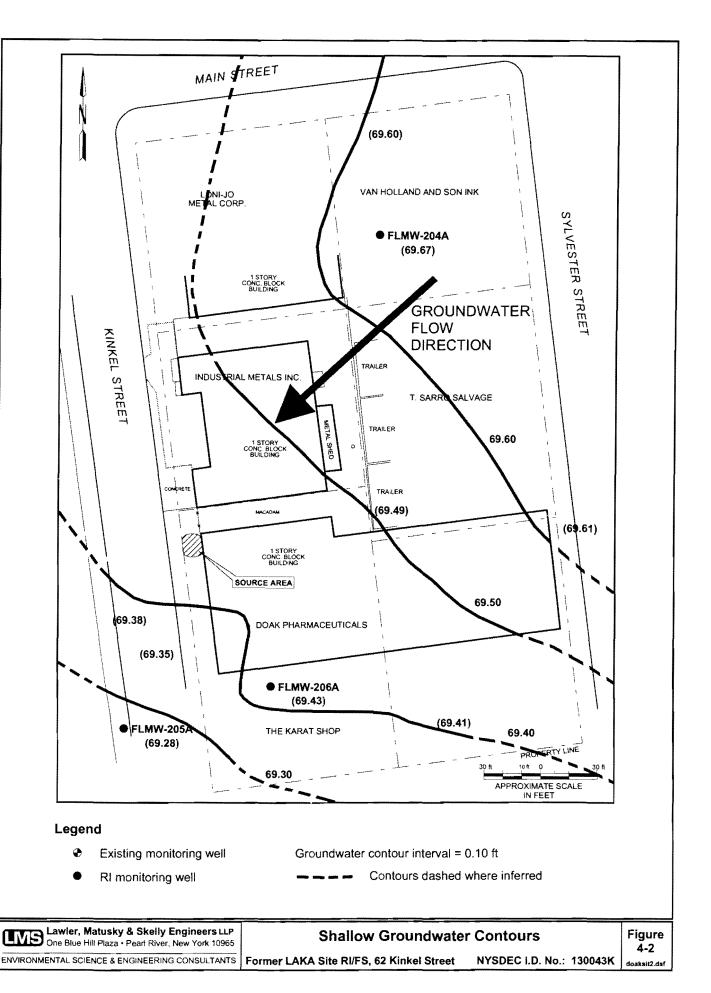

4.8.1 Regional Hydrogeology

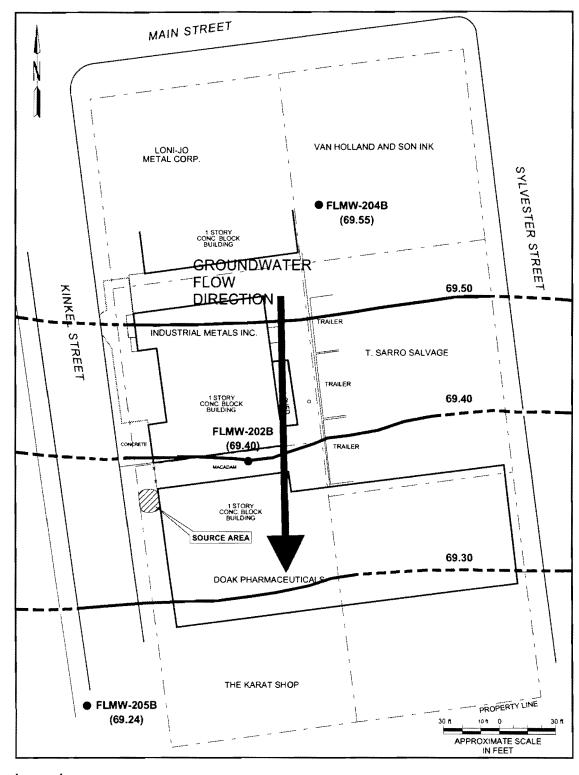

As outlined in the description of the regional geology of the area, there are three principal aquifers in the stratigraphic sequence of Long Island (Figure 4-1). The deepest of these aquifers is the Lloyd Sand member of the Raritan Formation, which is confined on the bottom by the metamorphic and igneous basement rock and by the overlying Raritan confining unit. The Lloyd is characterized as poorly to moderately permeable with hydraulic conductivities on the order of 10-ft/d. anisotropy ratio $(K_x:K_z)$ of the Lloyd aquifer is approximately 10:1 (USGS, 1989). Above the Lloyd aquifer is the Magothy Aquifer, confined on the bottom by the Raritan confining unit and, in places, on top by the Monmouth greensand or the Gardiners Clay. The Magothy is an extensive aquifer with horizontal hydraulic conductivities averaging about 50-ft/d and an anisotropy ratio of 100:1. The Jameco Gravel is a relatively thin water-bearing unit stratigraphically above the Magothy that is found only in the far western extent of Long Island. Overlying the Magothy is another extensive aquifer, the UGA (upper glacial aquifer). The UGA serves as the unconfined, water table aquifer from the ground surface to depths up to 700-ft and covers all of Long Island. Horizontal hydraulic conductivities in the UGA average over 200-ft/d with an anisotropy ratio of 10:1. Conductivities of UGA material from the southern half of the island (outwash) are about twice that of northern UGA material (morainal)(Buxton and Modica, 1992). Due to the southward dip of the sedimentary sequences, the younger UGA is in direct hydraulic connection with the Lloyd Sand Member aquifer as well as the Magothy Formation.

4.8.2 Study Area Hydrogeology

The hydrogeology of the area surrounding the former LAKA site is relatively simple, consisting of two main water-bearing units, the UGA and the deeper Magothy Aquifer. The Lloyd Sand Member of the Raritan Formation was not considered in this investigation as it is found at a depth over 600-ft in the study area. The UGA is an unconfined aquifer consisting of poorly sorted sands and gravels. The Magothy is the sole source aquifer for the study area and consists of finer sand, silt and small amounts of clay. Following NYSDEC and USEPA regulations, both the UGA and Magothy are protected as sole source aquifers on Long Island.

A confining layer between the UGA and the Magothy, the Gardiners clay, is not evident in the borings done during this investigation. Due to the lack of this confining layer, the UGA and Magothy are in direct hydraulic connection. Depth to water is about 50 to 55 ft below the ground surface in the study area and the hydraulic gradient is approximately .0006 ft/ft to the southwest (Figure 4-2 and Figure 4-3).

Former LAKA Site RI/FS, 62 Kinkel Street	ENVIRONMENTAL SCIENCE & ENGINEERING CONSULTANTS

Based on analysis of in-situ hydraulic tests performed during this investigation, hydraulic conductivity values for the UGA in the study area range from 58 to 391 ft/day. Hydraulic conductivity values based on slug tests conducted in deeper wells (Magothy Aquifer) were generally lower, ranging from 4 to 103 ft/day. A compilation of the data used in determining these values and a table of all hydraulic conductivities determined through in-situ testing are contained in Appendix D.

CHAPTER 5

NATURE AND EXTENT OF CONTAMINATION

5.1 PREVIOUS INVESTIGATIONS

5.1.1 NYSDEC PSA Sampling Data

In 1995 NYSDEC contracted LMS to conduct a Multisite PSA in the NCIA. Included in this investigation was an assessment of the Kinkel/Sylvester Street site in the central portion of the industrial area. This PSA investigation included the sampling of groundwater from various monitoring wells and the geoprobe soil sampling in the Kinkel/Sylvester Street block. Detailed file reviews of the past and present occupants of 62 Kinkel Street indicated that a tool and die manufacturer, LAKA Tool and Stamping and LAKA Industries occupied the site from 1971 to 1984. Nassau County Department of Health records indicated that LAKA Industries used 55 gal/year TCE for degreasing purposes.

Ground penetrating radar surveys conducted during the PSA of the 62 Kinkel Street property indicated that former leachpools were possible along the northern property line. Soil probe samples collected at a location off the northwest corner of the building indicated a possible contaminant source area. These samples were taken from sludge recovered at a depth of approximately 16 feet and contained extremely high levels of TCE (3,900 mg/kg) and cis-1,2-DCE (640 mg/kg). PCE-related contaminant levels appeared to decrease with depth, with an estimated concentration of 1.56 mg/kg present at a depth of 18 feet.

Groundwater probe samples taken at this location indicated high levels of PCE-related contamination at shallow and intermediate depths when compared to levels detected at the same depths in an upgradient point. The concentration at the shallow depth was 660 μ g/l compared to 36 μ g/l at the upgradient point while at the intermediate depth, concentrations were 4080 μ g/l in the source area and only 105 μ g/l upgradient. Monitoring well DOAK MW-3 was also sampled since it was, during the time of the investigation, the only well downgradient of the probable source area in the immediate vicinity. Contamination was also detected in groundwater from this well in the form of cis-1,2-DCE (340 μ g/l). Based on the high soil contamination and the emergence of a groundwater contamination plume from the site, LMS recommended that the former LAKA industries site be listed on the registry of hazardous waste sites.

5.1.2 NYSDEC Focused Remedial Investigation - 68 Kinkel Street

In April 1996, under contract to NYSDEC, ABB Environmental Services (ABB-ES) conducted field investigations for a Focused Remedial Investigation of the former Tishcon site at 68 Kinkel Street (upgradient of the former LAKA site). This investigation involved probe soil sampling at eleven points surrounding the former Tishcon site as well as the installation of three new shallow monitoring wells (MW-201, MW-202 and MW-203). ABB-ES sampled groundwater from these new wells and from three existing wells (DOAK MW-1, DOAK MW-2 and DOAK MW-3).

Soil samples collected from a probe point (GP-201) in the southeast corner of the former Tishcon site revealed the presence of PCE (0.077 mg/kg) and 1,1,1-TCA (0.011 mg/kg) at 0 to 2 ft bgs. In addition, these same contaminants were detected at 20 to 22 ft bgs in concentrations estimated at 0.011 mg/kg and 0.021 mg/kg, respectively.

Samples from GP-212, taken from within the building on the former Tishcon site, indicated the presence of PCE (0.064 mg/kg) and 1,1,1-TCA (0.012 mg/kg) at depths between 0 and 2 ft bgs. PCE levels were estimated at 0.002 mg/kg from 6 to 8 ft bgs.

Soil collected from GP-214, inside the building and south of GP-212, revealed methylene chloride at an estimated concentration of 0.002 mg/kg, PCE (0.066 mg/kg) and 1,1,1-TCA (0.012 mg/kg). Contamination was only detected at a depth of 0 to 2 ft bgs.

Relatively low levels ($<10 \mu g/kg$) of PCE, 1,1,1-TCA and TCE were found in the samples collected from the eight additional geoprobe locations on the former Tishcon site.

Groundwater samples collected from DOAK MW-1 showed the presence of 1,1,1-TCA (97 μ g/L) and PCE (52 μ g/L) as well as other VOCs at low levels (<10 μ g/L). Seven VOCs were detected in groundwater collected from DOAK MW-2 (on the former LAKA site) including 1,1,1-TCA at a concentration of 110 μ g/L. Relatively high concentrations of 1,2-DCA (estimated 370 μ g/L) and TCE (120 μ g/L) along with 1,1,1-TCA (21 μ g/L) and PCE (28 μ g/L) were detected in samples of groundwater from DOAK MW-3.

Sampling of MW-201 (upgradient of both the former Tishcon and LAKA sites), installed for the FRI conducted by ABB-ES, indicated the presence of very low levels of PCE (estimated 5 μ g/L) and other VOCs (estimated \leq 2 μ g/L). Higher concentrations of 1,2-DCA (62 μ g/L), 1,2-DCE (13 μ g/L), 1,1-TCA (89 μ g/L) and PCE (15 μ g/L) were found in MW-202 (in the alley between 62 and 68 Kinkel Street). MW-203 (across the street from 62 Kinkel Street) was also sampled and

found to contain 1,1-DCA (10 μ g/L), 1,2-DCE (total) (99 μ g/L), 1,1-TCA (33 μ g/L), TCE (19 μ g/L) and PCE (14 μ g/L) as well as other VOCs at low concentrations (estimated \leq 3 μ g/L).

5.1.3 Additional On-site Sampling

Geoprobe groundwater sampling was conducted by LMS during a 1993 Phase I Site Investigation at point GP-14 in front of the DOAK building. This was the only point sampled near the former LAKA site during the Phase I investigation. Contaminants detected at this point include PCE (479.3 μ g/L) and TCA (489 μ g/L) from water samples taken between the top of the water table (approximately 55 ft bgs and 65 ft bgs). PCE (143 μ g/L) and TCA (510 μ g/L) were also detected in water collected between 65 and 85-ft bgs. No contamination was found in water collected below 85-ft bgs. Groundwater samples were also collected from 56 wells in the New Cassel Industrial Area for the Phase I investigation, however, no wells in the Kinkel-Sylvester Street block were sampled.

In 1994 a Phase II Site Investigation was conducted in the NCIA to delineate contaminant plumes in groundwater below the area. This investigation included the sampling of soils from two geoprobe locations (SGP-108 and SGP-109) and two monitoring wells (DOAK MW-1 and DOAK MW-2) on the former LAKA site. PCE and TCA contamination was detected at low levels (< 2 μ g/l) in samples collected from 20 to 22-ft bgs from SGP-108 and SGP-109. Groundwater samples collected from DOAK MW-1 indicated PCE and TCA contamination at higher levels (102.8 μ g/l and 134 μ g/l, respectively). Still higher levels of contamination were found in groundwater from DOAK MW-2. PCE was detected at a concentration of 104.9 μ g/l and the level of TCA was found to be 578 μ g/l.

5.2 REMEDIAL INVESTIGATION ANALYTICAL RESULTS

5.2.1 Probe Sampling Data

5.2.1.1 Phase I Soil Probes.

VOC Sampling. A total of 26 locations were probed at the former LAKA site. Twelve points were located at or directly surrounding the known source leachpool at the northwest corner of 62 Kinkel Street. Twelve other points were located adjacent to the north and west faces of the building where additional source areas were suspected. Two probes were done into the drainage grate in the parking lot of 54 Kinkel Street to obtain sludge samples. A summary of VOC sampling results for

probe soil and sludge samples are contained in Tables 5-1 and 5-2, respectively. Field sampling logs are compiled in Appendix A.

From the twelve borings completed around the known source area, 37 samples were analyzed for VOCs to more accurately delineate the areal and vertical distribution of contamination. Of these twelve borings, only five locations exhibited VOC contamination other than Tentatively Identified Compounds (TICs) (Figure 5-1). Appendix H contains summary sheets of the analytical data from probe samples.

Boring FLGP-2 was completed to 24 ft bgs on 6 January 1998. FLGP-2 contained ethylbenzene (1.4 mg/kg), xylene (1.5 mg/kg) and low concentrations of TCE (0.011 mg/kg) at a depth of 1 to 2 ft bgs. Ethylbenzene (0.16 mg/kg), xylene (0.96 mg/kg) as well as low concentrations of TCE (0.003 mg/kg) and toluene (.004 mg/kg) were also detected at 8 to 9 ft bgs in FLGP-2.

On 6 January 1998, FLGP-3 was completed to refusal at 42 ft bgs in an unsuccessful attempt to sample water directly below the source area. Contamination was detected deeper here than in any other boring completed in the study area. At a depth of 4 to 5 ft bgs 1,2 DCE (0.034 mg/kg) and TCE (0.08 mg/kg) were detected. TCE was also found from 11 to 12 and 14 to 16 ft at levels of 0.024 and 0.009 mg/kg, respectively. From 16 to 17 ft bgs TCE (0.410 mg/kg) and PCE (0.028 mg/kg) were detected. TCE (0.680 mg/kg) and PCE (0.047 mg/kg) along with lower levels of xylene (0.022 mg/kg) and toluene (0.012 mg/kg) were detected at a depth of 20 to 21 ft bgs. In the deepest sample collected from FLGP-3, at 34 to 35 feet bgs, TCE (0.580 mg/kg), PCE (0.068 mg/kg), ethylbenzene (0.013 mg/kg), xylene (0.066 mg/kg) and toluene (0.012 mg/kg) were detected.

FLGP-4 was advanced to refusal at 48 ft bgs in another attempt at sampling groundwater below the source area. This boring was completed on 6 January 1998 at a location southeast of FLGP-3. TCE (0.017 mg/kg), ethylbenzene (0.099 mg/kg) and xylene (0.4 mg/kg) contamination was found in samples taken from this boring at a depth of 8 to 9 ft bgs. TCE (0.022 mg/kg) was also found in FLGP-4 from 13 to 14 ft bgs.

In samples collected from boring FLGP-7 (completed to 24 ft bgs on 6 January 1998), TCE (0.12 and 0.014 mg/kg) was detected at depths of 10 to 11 and 14 to 16 ft bgs, respectively. 1,2 DCE was also detected at a concentration of 0.080 mg/kg in the sample collected from 10 to 11 ft bgs.

The final boring surrounding the source area that exhibited contamination was FLGP-14, completed on 8 January 1998 to a depth of 41 ft bgs (refusal at hardpan or gravel layer). TCE was detected at a concentration of 0.084 mg/kg in a sample collected from 15 to 16 ft bgs.

- Post-digestion spike out of control limits; sample absorbance is less than 50% of spike absorbance.

A total of 40 VOC and 4 TAL metals/CN samples were collected from the twelve borings, completed 8 January to 12 January 1998, along the edge of the building's north and west faces (Figure 5-1). Eleven of these borings were completed to 24 ft depth bgs with one, FLGP-15, advanced to refusal at 42-ft bgs in attempt to sample groundwater. From the VOC samples submitted for analysis all results came back non-detect or varying amounts of TICs were detected. No identifiable VOCs were detected.

Two sludge samples were submitted to Accredited Labs from borings done through the drainage grate into the catch basin at 54 Kinkel Street (Figure 5-1). Due to the fluid nature of the sludge encountered here it was difficult to recover sample material from more than 2 ft below top of the sludge layer. The FLGP-12 sample was collected between 2 to 4 ft below the top of the sludge (approximately 12 to 14 ft bgs) and was analyzed for VOCs, SVOCs and TAL metals/CN. Results of the analysis for VOCs indicate that ethylbenzene (0.63 mg/kg) and xylene (1.2 mg/kg) along with TICs are present in the sludge. The sample collected from FLGP-13, on the opposite side of the drain at approximately the same depth as FLGP-12, indicate similar levels of contamination with ethylbenzene (0.63 mg/kg) and xylene (1.7 mg/kg) as well as TICs.

Sludge SVOC Sampling. Analysis of the FLGP-12 and 13 samples indicated the presence of several semi-volatile organic compounds in estimated concentrations exceeding the NYSDEC recommended soil cleanup objectives (Table 5-2). Benzo(a)anthracene was detected in both sludge samples at concentrations of 11 and 20 mg/kg, respectively. Chrysene was found in both FLGP-12 and 13 at concentrations of 9.9 and 17 mg/kg, respectively. Sludge samples FLGP-12 and 13 both contained benzo(b)fluoranthene (8.3 and 14 mg/kg, respectively) and benzo(k)fluoranthene (5.8 and 13 mg/kg, respectively) in levels exceeding NYSDEC standards. Benzo(a)pyrene was also found in both samples at concentrations of 7.3 and 14 mg/kg, respectively. Two other substances detected in levels exceeding the NYSDEC cleanup standards were indeno(1,2,3-c,d)pyrene at concentrations of 9.7 and 16 mg/kg, respectively and dibenzo(a,h)anthracene (5.2 and 9.1 mg/kg, respectively).

Metals Sampling. Fourteen samples were taken for TAL Metal and CN analysis from the probes completed in the source area. Six additional samples were analyzed for TAL Metals and CN from the twelve probe locations along the perimeter of the DOAK building and the two sludge samples collected from the catch basin in the parking lot at 54 Kinkel Street. Tables 5-1 and 5-2 summarize the analytical results for TAL Metals and CN from both probe soil and sludge samples.

Samples collected from FLGP-02 at a depth of 8 to 9 ft bgs showed levels of calcium (49,300 mg/kg) and magnesium (29,000 mg/kg) that exceed the NYSDEC soil cleanup objective levels

A sample collected at a depth of 18 to 19 ft bgs from FLGP-03 exhibited levels of nickel (97 mg/kg) that are above the 25 mg/kg standard established by NYSDEC.

Slightly elevated levels of mercury were detected in soil samples collected from probes FLGP-05 (9 to 10 ft bgs) and FLGP-06 (10 to 11 ft bgs). Concentrations of mercury were 0.31 and 0.28 mg/kg, respectively with the NYSDEC standard at 0.1 mg/kg and a maximum background concentration of 0.2 mg/kg.

Probe sample FLGP-07, collected at a depth of 10 to 11 ft bgs, showed concentrations of arsenic (14 mg/kg) that exceeded the maximum background concentration of 12.0 mg/kg used by the NYSDEC as the soil cleanup objective concentration.

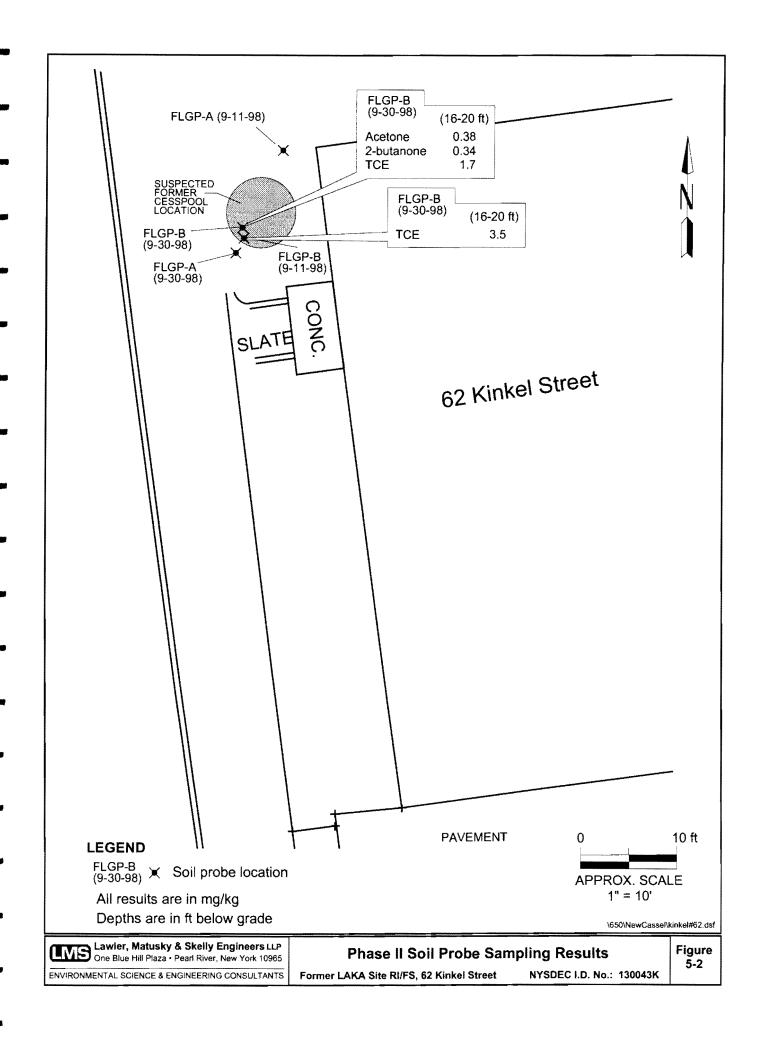

The soil sample collected from FLGP-14 at a depth of 15 to 16 ft bgs showed concentrations of three analytes, including cadmium (1.6 mg/kg), copper (138 mg/kg), and zinc (90 mg/kg) that exceed the soil cleanup objectives set by the NYSDEC.

Concentrations of cadmium (1.4 mg/kg), calcium (43,300 mg/kg), and magnesium (24,200 mg/kg) detected in FLGP-20 at a depth of 3 to 4 ft bgs are above the soil cleanup objective levels set by the NYSDEC.

TAL Metals detected in sludge samples collected from FLGP-12 and FLGP-13 at levels exceeding the NYSDEC sediment criteria standards include cadmium (10 and 9.6 mg/kg, respectively), lead (1,520 and 1,120 mg/kg, respectively), silver (7.1 and 5.8 mg/kg, respectively), copper (335 and 232 mg/kg, respectively), and zinc (747 and 815 mg/kg, respectively).

5.2.1.2 Phase II Soil and Groundwater Probes.

VOC sampling. Five additional probes were completed in Phase II. Four of the additional points were completed for soil samples in the sludge zone at the source area and the other probe was completed to sample groundwater at three intervals below the source area. Although four additional soil probes were completed samples were submitted for analysis from only two of the probes, FLGP-B(9-11-98) and FLGP-B(9-30-98). Materials collected from FLGP-A(9-11-98) and FLGP-A(9-30-98) exhibited very low PID readings and were not submitted for analysis. Figure 5-2 shows a plan view of the soil probe sample locations and results of the subsequent analysis. A total of three water samples were also submitted for analysis from the groundwater probe completed in Phase II. The location and analytical results for these water samples are presented in Figure 5-3. Tables 5-3 and 5-4 contain the analytical results for the soil and water samples, respectively. Field sampling logs for the soil samples are found in Appendix A.

- ND Not detected at analytical detection limit.

Probe FLGP-B was completed to a depth of 24 ft bgs on 11 September 1998. One sample of the material recovered from the probe at a depth of 16-20 feet was submitted for VOC analysis, Figure 5-2 is a plan view of the sample locations. This sample exceeded the specified holding temperature for VOC compounds since it was not received promptly at the analytical laboratory. One compound, TCE (3.5 mg/kg), was found to exceed soil cleanup objective levels. Other compounds detected in the analysis of this sample included acetone (0.022 mg/kg), PCE (0.025 mg/kg), toluene (0.003 mg/kg), ethylbenzene (0.001 mg/kg), and cis-1,2-DCE (0.100 mg/kg). Methylene chloride was also detected in the sample at a concentration of 0.016 mg/kg but was found in associated blanks as well and is believed to be due to laboratory contamination.

A second probe, designated FLGP-B, was completed to a depth of 28 ft bgs on 30 September 1998 to collect a sample to replace the one that was collected 11 September 1998. This probe was located very close to the original sample location and the sludge zone beneath the source area was again encountered in the 16-20 feet bgs interval. Resampling of this interval revealed three compounds in concentrations exceeding soil cleanup objectives, acetone (0.38 mg/kg), 2-butanone (0.34 mg/kg), and TCE (1.7 mg/kg). 1,2-DCE (total) (0.03 mg/kg), PCE (0.081 mg/kg), and toluene (0.03 mg/kg) were also detected in the sample. Again, methylene chloride (0.093 mg/kg) was detected in the sample as well as associated blanks and is believed to result from laboratory contamination.

Probe FLGP-W1 was completed on 18 September 1998 and groundwater samples from three discrete intervals were collected. Again, due to a problem at the analytical laboratory, these samples did not remain at the proper holding temperature before analysis.

Groundwater from the shallowest sampling interval (62-63 feet bgs) did not contain any compounds in concentrations that exceed NYSDEC Class GA Standards. However, several compounds, including acetone (48 μ g/l), 1,1-DCE (2 μ g/l), 1,1-DCA (2 μ g/l), 1,2-DCE (total)(2 μ g/l), 2-butanone (7 μ g/l), 1,1,1-TCA (5 μ g/l), TCE (4 μ g/l), and PCE (2 μ g/l), were detected in the sample. Methylene chloride (4 μ g/l) was again detected in both the sample and associated blanks and is believed to be a result of laboratory contamination.

Concentrations of four compounds detected in the intermediate depth (72-73 feet bgs) groundwater samples exceed the NYSDEC Class GA Standards. These compounds include 1,1-DCE (10 μ g/l), 1,1-TCA (16 μ g/l), TCE (14 μ g/l), and PCE (11 μ g/l). In addition, acetone (49 μ g/l), 1,1-DCA (4 μ g/l), 1,2-DCE (total)(3 μ g/l), and 2-butanone (8 μ g/l) were detected at levels that did not exceed the standards. Methylene chloride was again detected in the sample (4 μ g/l) and associated blanks.

At the deepest sampled interval (92-93 feet bgs), acetone (210 μ g/l), 1,1-DCA (7 μ g/l), 1,2-DCE (total)(17 μ g/l), 1,1,1-TCA (7 μ g/l), TCE (8 μ g/l), benzene (2 μ g/l), and PCE (7 μ g/l) levels exceed NYSDEC Class GA Standards for groundwater. 1,1-DCE (2 μ g/l) and toluene (2 μ g/l) were also present in the sample at levels that did not exceed the groundwater standards. Methylene chloride was again present in both the sample (4 μ g/l) and associated blanks.

5.2.2 Groundwater Sampling Data

Groundwater samples were collected from thirteen wells surrounding the former LAKA site including the seven newly installed wells and six that existed prior to this investigation. Each well was sampled for TCL VOCs, TAL Metals and CN. Analytical data summary sheets for all groundwater samples can be found in Appendix G.

5.2.2.1 *VOC Sampling.* A summary of the groundwater sampling results for VOCs are presented in Table 5-5. Monitoring well FLMW-206A, located in the parking lot at 54 Kinkel Street, is downgradient of the former LAKA site and was sampled on 9 February 1998. The VOCs 1,2-DCE (total) (110 μ g/l), 1,1-DCA (12 μ g/l), TCE (45 μ g/l) and 1,1,1-TCA (38 μ g/l) were detected in the sample. In addition, 1,1-DCE and PCE were detected at estimated levels less than 10 μ g/l.

DOAK MW-3, off the southwest corner of the building at 62 Kinkel Street, was also sampled on 9 February 1998. 1,2-DCE (total) (94 μ g/l), 1,1-DCA (25 μ g/l), TCE (29 μ g/l), 1,1,1-TCA (39 μ g/l) and PCE (10 μ g/l) were found in groundwater collected from DOAK MW-3. In addition 1,1-DCE levels were estimated at 1 μ g/l.

MW-201 is located upgradient of the former LAKA site on Main Street between Kinkel and Sylvester Streets. Sampling of this well was conducted on 10 February 1998 and revealed only relatively low levels of VOC contamination. PCE, TCE and 1,1,1-TCA were detected at estimated concentrations of 9, 2 and 3 µg/l, respectively.

Sampling of FLMW-205A also occurred on 10 February 1998. This new shallow well is located across Kinkel Street, southwest of the former LAKA site. The VOCs 1,2-DCE (total)(98 μ g/l), TCE (36 μ g/l) and toluene (10 μ g/l) were detected in groundwater samples collected from this well. 1,1,1-TCA, PCE and total xylenes were also detected at estimated concentrations of 7, 3 and 4 μ g/l, respectively.

On 11 February 1998, the new deep well FLMW-206B was sampled. This well is also located on the south side of the building at 62 Kinkel Street, downgradient of the former LAKA site, in the

b - Found in associated blanks.

⁻ Estimated concentration; compound present below quantitation limit.

ND - Not detected at analytical detection limit.

parking lot at 54 Kinkel Street. Sampling of this well revealed the presence of a wide variety of VOCs in the groundwater. 1,1-DCE (18 μ g/l), 1,1-DCA (28 μ g/l), 1,2-DCE (total)(23 μ g/l) were present in the sample as were 1,1,1-TCA (49 μ g/l), TCE (34 μ g/l) and PCE (47 μ g/l). Concentrations of several other compounds were estimated including chloroform (1 μ g/l) and toluene (2 μ g/l).

FLMW-202B was sampled on 11 February 1998. Located in the alley north of the 62 Kinkel Street, FLMW-202B is considered an upgradient well and is the deepest of the wells sampled during this investigation (approximately 120-ft bgs). Two VOCs were detected at concentrations above 5 μ g/l, TCE (19 μ g/l) and PCE (38 μ g/l). Three other VOCs were found at concentrations estimated to be less than 5 μ g/l, 1,2-DCE (total)(2 μ g/l), 1,1,1-TCA (3 μ g/l) and toluene (2 μ g/l).

The shallow counterpart to FLMW-202B, MW-202, was also sampled on 11 February 1998. This well was installed in 1996 and is also located upgradient of the former LAKA site in the alley north of 62 Kinkel Street. VOCs detected in groundwater samples from MW-202 include 1,1-DCA (55 μ g/l), 1,1,1-TCA (49 μ g/l) and PCE (14 μ g/l). Concentrations of 8 and 4 μ g/l were estimated for two other analytes, total 1,2-DCE and TCE, respectively.

The final well sampled on 11 February 1998 was FLMW-204B, upgradient of the former LAKA site in the alley west of 71 Sylvester Street. Analysis of groundwater samples collected from this well revealed the presence of TCE (35 μ g/l) and PCE (33 μ g/l). Additional contaminants included 1,1-DCE, total 1,2-DCE and 1,1,1-TCA at estimated concentrations of 1, 6 and 5 μ g/l, respectively.

The existing monitoring well DOAK MW-2 was first to be sampled on the final day of sampling, 12 February 1998. This well is located cross-gradient to the known source area, in the employee parking lot at 67 Sylvester Street. Analysis of samples taken from this well indicated the presence of PCE (15 μ g/l) and 1,1,1-TCA (43 μ g/l). Several other compounds, including 1,1-DCE (4 μ g/l), 1,1-DCA (8 μ g/l), 1,2-DCE (total)(1 μ g/l), TCE (4 μ g/l) and toluene (2 μ g/l) were detected at low estimated concentrations.

DOAK MW-1, near the east entrance to the building at 67 Sylvester Street, was also sampled on 12 February 1998. This well is another relatively shallow well (approximately 65-ft bgs) that is cross-gradient from the known source area at the northwest corner of the building. Sampling results from this well were similar to those from DOAK MW-2 with higher levels of PCE (56 μ g/l) and 1,1,1-TCA (53 μ g/l) detected. As was the case in samples taken from DOAK MW-2, 1,1-DCE (8 μ g/l), 1,1-DCA (6 μ g/l), 1,2-DCE (total)(7 μ g/l), TCE (6 μ g/l) and toluene (8 μ g/l) were detected at relatively low estimated concentrations.

The upgradient shallow well, FLMW-204A, was the third well to be sampled on 12 February 1998. This well is also located in the alley west of 71 Sylvester Street. Groundwater samples collected here indicated the presence of PCE (14 μ g/l) and very low estimated concentrations of 1,1,1-TCA (5 μ g/l), TCE (7 μ g/l) and toluene (2 μ g/l).

FLMW-205B, a deep well located across Kinkel Street from the parking lot at 54 Kinkel Street was next to be sampled on 12 February 1998. FLMW-205B is nearly directly downgradient from the known source area on the former LAKA site. Several VOCs were found in samples collected from this well, including 1,1-DCE (21 μ g/l), 1,1-DCA (13 μ g/l), 1,2-DCE (total)(32 μ g/l), 1,1,1-TCA (65 μ g/l), TCE (99 μ g/l) and PCE (110 μ g/l). Chloroform (3 μ g/l) and toluene (6 μ g/l) were also detected at low estimated concentrations.

The final well sampled was MW-203, located in the parking lot at 65 Kinkel Street (across the street from the west entrance to the building at 62 Kinkel Street). MW-203 is cross-gradient from the known source area at the former LAKA site. However, due to the proximity of MW-203 to the known source area, it is possible that dispersion of any contaminant plume originating at the source area impacted the groundwater in this well. VOCs detected in samples from MW-203 include 1,2-DCE (total)(66 μ g/l), 1,1,1-TCA (21 μ g/l), TCE (14 μ g/l), PCE (11 μ g/l) and toluene (12 μ g/l). 1,1-DCA was also detected at an estimated concentration of 8 μ g/l.

5.2.2.2 *Metals Sampling*. All of the above wells were also sampled for TAL Metals and CN. Analysis for a total of 23 metals and cyanide were done for these samples. Table 5-6 shows a summary of the sampling results for these analytes in groundwater collected from the thirteen sampled wells.

Aluminum concentrations in eight wells were found to exceed the maximum natural ambient groundwater level of 1,000 μ g/l. FLMW-204A,-205A, and -206A exhibited concentrations of 16,700 μ g/l, 54,600 μ g/l, and 9,070 μ g/l, respectively. MW-201, -202, and -203 had concentrations of 5,490 μ g/l, 5,010 μ g/l, and 30,800 μ g/l, respectively. DOAK MW-2 and DOAK MW-3 also had elevated aluminum concentrations of 1,210 μ g/l and 1,600 μ g/l, respectively.

Similarly, sodium concentrations were higher than NYSDEC standards for water collected from eight wells. The sodium concentration in DOAK MW-1 was 50,600 μ g/l. Concentrations of sodium in MW-201 and MW-203 were 29,800 μ g/l and 28,400 μ g/l, respectively. From the newly installed wells, FLMW-202B, -204B, -205A, -205B, and -206B all showed sodium levels exceeding the standard. Concentrations of sodium in water from these wells were 33,900 μ g/l, 23,900 μ g/l, 26,100 μ g/l, 24,900 μ g/l, and 23,700 μ g/l, respectively. Groundwater from all wells

sampled exceeded the NYSDEC standard for combined iron and manganese concentrations of 500 $\mu g/l$. Beryllium concentrations of 4.7 $\mu g/l$ in groundwater sampled from FLMW-204A were found to exceed the guidance value of 3.0 $\mu g/l$ set by the NYSDEC. Groundwater from DOAK MW-2 indicated concentrations of antimony (55.1 $\mu g/l$) that exceed the NYSDEC guidance value of 3.0 $\mu g/l$.

Groundwater collected from MW-203 exceeds the NYSDEC standard for arsenic, chromium, and lead with concentrations of 34.1 μ g/l, 92.0 μ g/l, and 48.6 μ g/l, respectively. Lead (73.0 μ g/l) and chromium (85.8 μ g/l) levels in FLMW-205A were also found to be above NYSDEC standards. Zinc levels in groundwater from MW-202 were 976 μ g/l, exceeding the NYSDEC standard of 300 μ g/l.

CHAPTER 6

SUMMARY AND CONCLUSIONS

6.1 FIELD INVESTIGATION

The FRI at the former LAKA site was performed to further characterize the nature and extent of the contamination discovered during the previous PSA. The field investigation included the completion of a number of probes, monitoring wells, and the sampling of drainage structures and monitoring wells.

A total of 30 probe locations were sampled and 69 samples were analyzed for VOC's and SVOC's. A majority of these probes were installed in the suspected location of a former leachpool which was found to be contaminated during the PSA. During the probing at the site bottom sludges were collected and analyzed from a drainage structure located at 54 Kinkel Street. In addition, three groundwater samples were collected from a probe point in the suspected former leachpool location.

A total of 7 additional monitoring wells were installed at the site. These included 3 shallow and 4 deep monitoring wells to determine the vertical distribution of the contaminants. The shallow wells were completed near the bottom of the upper glacial aquifer while the deep wells were set into the top of the Magothy Aquifer at approximately 110 ft below the ground surface. After the wells were installed and developed the wells were sampled along with 6 existing wells from previous on-site and off-site investigations. Each of the groundwater samples were analyzed for VOCs and metals.

6.2 DATA INTERPRETATION

The site history for the former LAKA site indicates that the main contaminants of concern are VOCs and SVOCs. The VOCs are primarily halogenated volatile organic compounds used in degreasing while the SVOCs were used as lubricants or cutting oils. It was also believed that metals contamination may be present since the former operations at the site included machining and fabrication of metal parts. All samples collected during the focused RI were analyzed for VOCs, and portions for SVOCs and metals. The following data interpretation includes each of the media sampled including the subsurface soils, drainage structure sediments, and the groundwater.

6.2.1 Subsurface Soils

A total of 69 soil samples were collected from the soil probe locations. The results indicated the presence of acetone above the cleanup objectives at FLGP-02 (1-2 ft) and FLGP-02 (8-9 ft). Xylene was also detected above the soil cleanup objective at FLGP-02 (1-2 ft). FLGP-B (9-30-98), collected during the second phase of soil probing, contained acetone, 2-butanone, and TCE at concentrations above soil cleanup objective levels in the 16-20 feet bgs interval.

Nickel, arsenic and mercury were found above the cleanup objectives in FLGP-03 (18-19 ft) and are believed to be related to site activities. Only nickel was found to exceed both the cleanup objective and eastern background soil concentrations in FLGP-03. Several other metals including iron, mercury, and cadmium were found above the recommended cleanup objectives in the soil probe samples. Iron was found above the cleanup objective in 16 of the samples but the values are within the eastern background soil concentrations and are believed to represent site background levels. Mercury was detected above the recommended soil cleanup objective in 10 samples (including FLGP-02 and FLGP-03). The detected concentrations are slightly elevated above eastern background soil concentrations and are believed to be related to activities at the site. Cadmium was found in excess of the recommended soil cleanup objective in two of the samples, FLGP-14 (15-16 ft) and FLGP-20 (3-4 ft), and are believed to be related to activities at the site.

Based on the observations during the PSA and the RI soil probes it appears the former leachpool which was located off the northwest corner of the building was likely abandoned when the existing building was connected to the county sewer system. Records or information on when the building was connected to the county sewer or how the leachpool was cleaned and abandoned were not found. The sampling results support this in that only limited hot spots of VOC contamination were found in the former pool location. The other soil probes which were installed across the site did not indicate that additional VOC source areas are located in the areas that were sampled. Although several metals were detected in excess of recommended cleanup objectives it is not believed that significant source areas of metals contamination exist on-site which may pose a threat of leaching to the groundwater. The levels of metal contamination are typical of a highly industrialized area.

6.2.2 Drainage Structure

Two bottom sludge samples were collected from the drainage structure at 54 Kinkel Street. In this structure the depth to standing water was approximately 4 ft with a water layer of 8 ft followed by 2 ft of very soft loose sludge. In FLGP-12 xylene was found at the recommended cleanup objective (1.2 ppm). Eight SVOCs were found in excess of the recommended soil cleanup objective including phenanthere, benzo(a)anthracene, chyrsene, benzo(b)flouranthene, benzo(k)flouranthene,

benzo(a)pyrene, indo(1,2,3-c,d)pyrene, and dibenzo(a,h)anthracene. Both sludge samples cóllected from the drainage structure contained elevated levels of cadmium, chromium, lead, mercury, and nickel above the recommended cleanup objectives.

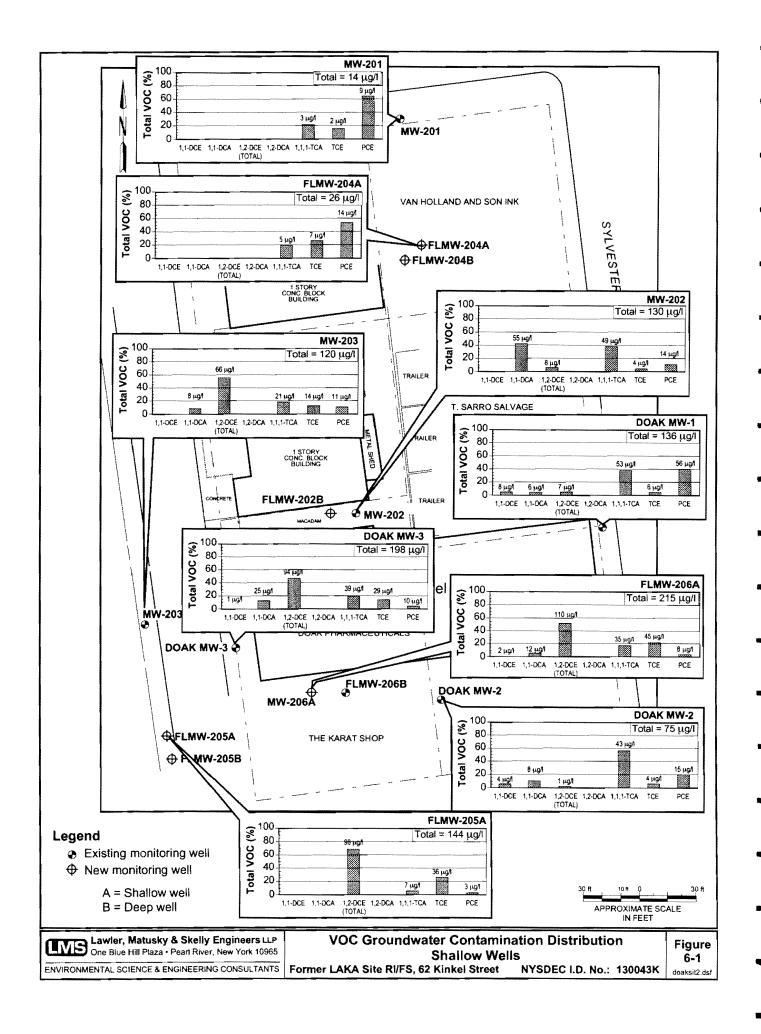

The analytical data indicates that the existing drainage structure located in the parking lot at 54 Kinkel Street contains elevated levels of VOCs and SVOCs which exceed the recommended cleanup objective for these compounds. The drainage structure also contains elevated levels of metals including chromium, cadmium, lead, and mercury above the recommended cleanup objectives. It is not known if the presence of these contaminants are related to activities associated with the former LAKA operation. Based on the location of the drainage structure any runoff from the former LAKA site along the southern side of the building would be directed to this structure. However, the noted contamination may be typical of stormwater runoff in an urban/industrialized area.

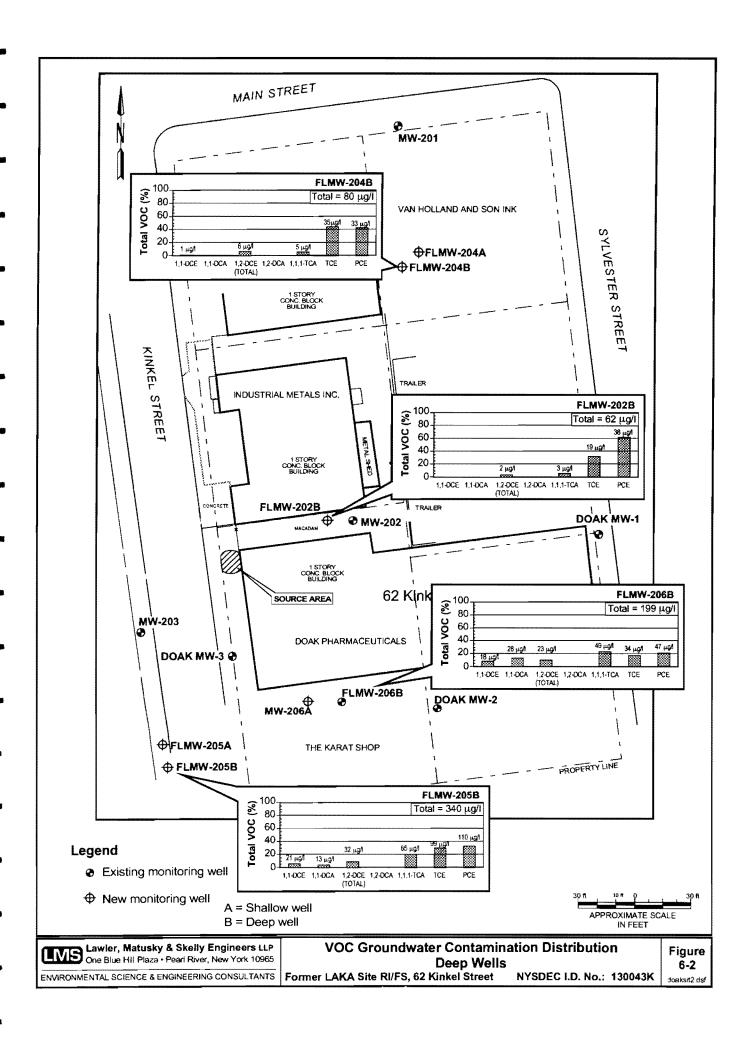

6.2.2 Groundwater

A total of 13 monitoring wells were sampled during the focused RI. The monitoring wells sampled include both shallow and deep monitoring wells. Analytical data from the 13 wells indicate that VOCs in excess of the Class GA standards are found in all of the wells including the upgradient wells. The concentrations are greater in the downgradient wells and in the deeper monitoring wells.

In the two upgradient shallow wells (MW-201 and FLMW-204A) total VOCs were 14 μ g/l and 26 μ g/l respectively; PCE was the primary contaminant present making up over 50 percent of the total VOCs (Figure 6-1). In the deeper upgradient well total VOCs were 80 μ g/l with TCE and PCE the primary contaminants (Figure 6-2). The presence of these compounds in the upgradient wells indicates that an upgradient source of contamination exists north of Main Street. One additional upgradient well (Doak MW-1) also contained significant levels of contamination and is also likely affected by the unknown upgradient source.

The most upgradient on-site wells are MW-202 and FLMW-202B. The deeper wells showed similar concentrations and a similar contaminant distribution as the upgradient well (FLMW-204B) (Figure 6-2). The shallow well was found to contain total VOC concentrations significantly higher than the upgradient wells and a different suite of contaminants including 1,1-DCA and 1,1,1-TCA (Figure 6-1). The increased concentrations at the shallow depth and the different contaminant suite indicates that the LAKA site or the former Tishcon site at 68 Kinkel has contributed to the groundwater contamination in this area. The site history for the LAKA site does not indicate that 1,1,1-TCA was used while Tishcon is a known to use large amounts of that compound.

Six monitoring wells are located immediately downgradient of the Former LAKA site including 4 shallow wells (MW-203, Doak MW-3, FLMW-205A, and FLMW-206A) and two deep wells (FLMW-205B and FLMW-206B). Similar concentrations are found in all of the shallow wells and 1,2-DCE, a breakdown product of PCE, is the primary contaminant of concern (Figure 6-1). In each of the shallow wells total 1,2-DCE accounts for over 40 percent of the total VOCs. The total VOC concentrations in the two deep wells were 340 μg/l (FLMW-205B) and 199 μg/l (FLMW-206B). The highest concentration was detected in FLMW-205B which is in a direct downgradient position of the former leachpool on the northwest corner of the building. The distribution of individual contaminants in these two wells are similar. In both FLMW-205B and FLMW-206B, 1,1,1-TCA, TCE, and PCE account for approximately 60 percent of the VOCs, with similar percentages of the individual contaminants (Figure 6-2).

Groundwater collected from the probe point near the suspected source area exhibited contamination at the three intervals that were sampled. In the shallow interval (62-63 feet bgs), no compounds were detected in concentrations above the NYSDEC Class GA groundwater standards. 1,1-DCE, 1,1,1-TCA, TCE, and PCE were all present in levels above Class GA standards at the intermediate interval (72-73 ft bgs). Groundwater collected from the deepest interval (92-93 ft bgs) contained levels of acetone, 1,1-DCA, 1,2-DCE (total), 1,1,1-TCA, TCE, benzene, and PCE in excess of the standards. However, the results from these groundwater probes are biased low due to problems associated with the analytical laboratory.

Based on the results of the groundwater sampling and analysis, past activities at the former LAKA site have contributed to the known groundwater contamination in this area of the NCIA. The contamination has affected both the upper glacial aquifer and the upper zones of the Magothy Aquifer. The analytical results from the upgradient wells indicates that additional upgradient groundwater contamination has migrated onto the former LAKA site. The exact vertical and horizontal limits of the plume could not be determined due to the presence of upgradient groundwater contamination. The distribution of individual contaminants suggests that both a source of 1,1,1-TCA and TCE/PCE related compounds are present upgradient.

6.3 POTENTIAL EXPOSURE PATHWAYS

The sampling and analysis conducted during the remedial investigation identified limited subsurface soils and drainage structure sediment contamination at concentrations greater than the NYSDEC Soil Cleanup objectives. Since most of the property is paved and is currently used for industrial purposes possible exposure pathways to the contamination are limited. If warranted by a final NYSDEC review of the data a detailed exposure assessment can be conducted to address possible exposure pathways to on-site workers and the public.

Based on the groundwater sampling data the site appears to be contributing to the groundwater contamination in the NCIA. Currently there are no on-site pathways of exposure to the groundwater due to the fact that groundwater is not utilized in any capacity, including as a source of drinking water. Pathways within the NCIA are also not present since there is no documented groundwater use within the industrial area. The potential for exposure pathways downgradient of the NCIA through the groundwater are being addressed by other NYSDEC investigations due to the presence of multiple sources of contamination within the NCIA.

6.4 REMEDIAL ACTION OBJECTIVES

Remedial action objectives are developed for a site to determine the levels to which contaminant concentrations must be reduced to protect human health and environment. The remedial action levels for this site are based on established NYSDEC recommended soil cleanup objectives and NYSEC Class GA groundwater standards for each of the contaminants of concern. The results of exposure assessment if conducted could be used to further refine the remedial action objectives for the soils.

6.5 QUANTITIES OF CONTAMINATED MEDIA

6.5.1 Subsurface Soils and Drainage Structure Sediments

Although detailed exposure assessments were not conducted for the subsurface soils and drainage structure sludges, contaminants in these media are a source of continued groundwater contamination through leaching. Establishment of remedial action objectives for these media are based on the prevention of the continued migration of the contaminants present in the soils to the groundwater. Based on the limited amount of soils found in excess of the cleanup objectives approximately 22 cubic yards of contaminated soils are found near the former leachpool area. In addition to the soils another 4 cubic yards of contaminated sludges are found in the drainage structure located at 54 Kinkel Street. The quantity of contaminated subsurface soils and drainage structure sludges maybe revised based on the results of the exposure assessment.

6.5.2 Groundwater

The quantity of contaminated groundwater is based on the NYSDEC Class GA groundwater standards which are applicable to the upper glacial and Magothy Aquifer which are found below the site. The compounds found in the groundwater that exceed the Class GA groundwater standard are 1,1,1-TCA, TCE, PCE and their breakdown products. Based on the measured concentrations the

PCE plume which exceeds the Class GA standards is much larger then the plumes of the other compounds. Based on the limited off-site data the total area of the PCE plume in the vicinity of the site is approximately 140,000 square ft. Assuming the plume extends to approximately 150 feet below the ground surface and an average porosity of .20, the total estimated quantity of contaminated groundwater is 4.2 million gallons.

DATA USEABILITY REPORT

This useability report covers the analytical results, submitted by Accredited laboratories, Inc. (Accredited), for the field sampling investigation, conducted by Lawler, Matusky & Skelly Engineers LLP (LMS) in February 1998 at the Laka site. The analytical report submitted by Accredited, sample designation group (SDG) 8342 was validated by Nancy J. Potak's Data Validation. LMS reviewed the data validator's final report and assessed the analytical data against the project data quality objectives (DQOs) in preparation of this report. The laboratory performed all of the necessary actions in order to provide the most representative data and where resulting quality control (QC) data did not fall within protocol requirements the reported data have been appropriately qualified. Overall, the data submitted by Accredited met project DQOs and are useable to characterize levels of select environmental contaminants in samples collected as part of the Laka investigation.

A total of 14 groundwater samples were collected as part of the Laka investigation and analyzed for contract laboratory program (CLP) target compound list (TCL) volatile organic compounds and CLP target analyte list (TAL) metals and cyanide. All of the analyses were conducted in accordance with the most recent version of the New York State Department of Environmental Conservation (NYSDEC) Analytical Services Protocol (ASP).

In general the analytical data submitted by Accredited were compliant with the established protocols. These instances where the reported data were noncompliant are described in the data validator's report. This report presents a discussion of any impacts that noncompliant data and any other issues raised by the validator may have on the useability of the reported results.

Volatile Organic Compound Analysis

Groundwater samples submitted to Accredited were analyzed for TCL VOCs in accordance with NYSDEC ASP CLP Method 95-1. All of the holding times, QC, and instrument calibration requirements were met with the few exceptions described in detail in the data

validator's report. Where reported concentrations may have been affected by QC failures the data useability is discussed below:

- 1. The recoveries of toluene in the matrix spike (MS) and matrix spike duplicate (MSD) were slightly outside of the required quality assurance limits. Data useability is unaffected and no qualification is indicated.
- 2. Methylene chloride was detected in the method blanks as well as the field and trip blanks at levels which were comparable to detections in field samples. The presence of methylene chloride in the samples, therefore, is not considered to be representative of site conditions and the validator rejected all detections of the compound. Methylene chloride was removed, therefore, as a detected compound in the final data summary table prepared by LMS.
- 3. Instrument detection limits (IDLs) were determined 8 months ago which is outside of the NYSDEC ASP requirement of 6 months. Data useability is unaffected and no qualification is required.

Target Analyte List Metals plus Cyanide

- 1. Chromium was detected in the method blank at a concentration which slightly exceeded the contract required detection limit (CRQL). The presence of chromium in the method blank indicates a source of chromium contamination which is not associated with the environmental samples. Samples were not re-run by the laboratory as required by protocol. Based upon the NYSDEC ASP quality assurance manual, the validator was required to reject all chromium data which is less than 10 times the blank concentration ($< 100 \mu g/l$). Data is useable, however, to indicate the relative magnitude of chromium in the samples.
- 2. Recovery of the CRQL zinc standard was slightly low indicating that for samples which reported low-level zinc concentrations, those concentrations are estimated and may be slightly biased low.

- 3. Iron was detected in low concentrations in the field blank which did not affect data useability or reporting.
- 4. Duplicate analyses resulted in a elevated relative percent difference for zinc. All zinc concentrations reported for the environmental samples, therefore, were considered to be highly estimated. Data is useable to indicate the relative concentration of this parameter in groundwater.
- 5. Results of the total serial dilution analysis indicated the recoveries of aluminum, barium, calcium, iron, magnesium, manganese, and sodium were outside of the acceptable quality assurance limits and therefore should be considered estimated. data is useable to show the relative concentrations of theses analytes in groundwater.

SUMMARY OF THE ANALYTICAL DATA VALIDATION For NYSDEC LAKA

LAWLER, MATUSKY & SKELLY ENGINEERS LLP

APR 1 3 1998

Water samples were received for analyses of the volatile organic TCL analyte list by NYS DEC ASP protocols. A complete analytical validation was performed based upon the following parameters:

- Data Completeness
- * GC/MS Tuning
- * Holding Times
- * Calibrations
- Laboratory Blanks
- * Field Blanks
- * Trip Blanks
- * System Monitoring Compound Recoveries
- * Internal Standard Recoveries
 - Matrix Spike / Matrix Spike Duplicate
- * Blank Spike
- * Compound Identification
- * Compound Quantitation
 - Method Detection Limit
- * Indicates that all criteria were met for this parameter.

DATA VALIDATION SUMMARY

Many of the pages were out of the reporting order specified in the NYS DEC ASP protocols.

The specific NYS DEC ASP forms for the instrument detection limits, "Sample Identification and Analytical Requirement Summary" (B-200) and "Sample Preparation and Analysis Summary" (B-201) were not included in the laboratory's analytical package, though similar form were submitted by the laboratory. The laboratory has been asked to submit the revised forms.

The minor problems with the matrix spike should be noted.

No other problems were found with the analyses of these samples which would affect the end use of the data.

Nancy J. Potak April 8, 1998

Holding Times

All samples were analyzed within the 10 day holding time required by the NYS DEC's ASP program.

Tunes

No problems were found with any of the instrument tunes.

The less stringent EPA tune requirements were noted on the laboratory's FORM V. All of the NYS DEC ASP tune requirements were met in the analyses of these samples.

System Monitoring Compound Recoveries

All system monitoring compound recoveries were within the NYS DEC's ASP quality assurance limits.

Calibrations

No problems were detected with either the initial or continuing calibrations.

Matrix Spike / Matrix Spike Duplicate

Sample MW-201 (Lab. #: 9801459) of this sample delivery group was used for the matrix spike and matrix spike duplicate. All recoveries and RPDs were within the required quality assurance limits with the exceptions of the recoveries of the toluene matrix spike duplicate (160%) and the toluene RPD (35%). The data were not qualified for these problems with the spike recoveries and RPDs.

Blank Spike

All blank spike recoveries were within the required quality assurance limits.

A blank spike duplicate was also analyzed and all recoveries and RPDs in this sample were within the standard NYS DEC ASP volatile organic quality assurance limits.

Method Blanks

Methylene chloride (2J and 3J ug/l) were detected in both method blanks associated with the analyses of these samples. This compound was negated according to EPA data validation protocols whenever it was detected in a sample of this delivery group.

Trip Blank

Only low concentrations of methylene chloride were detected in each of the three trip blanks associated with the samples of this delivery group. This compound was negated in all of the trip blanks due to its presence in the associated method blank.

Field Blank

Only low concentrations of methylene chloride were detected in each of the three field blanks associated with the samples of this delivery group. This compound was negated in all of the field blanks due to its presence in the associated method blank.

Internal Standard Areas and Retention Times

All internal standard areas and retention times were within the required quality assurance limits.

Instrument Detection Limits

The laboratory's instrument detection limits were determined 8 months prior to the analyses of the samples of this delivery group. The NYS DEC ASP requires that these be determined every 6 months.

No other problems were detected with the laboratory's reported instrument detection limits.

Sample Results

The unknown non-target compounds were flagged with the "N" qualifier by the laboratory. This qualifier is reserved for non-target compounds whose identities have been positively confirmed by GC/MS. This qualifier should not be used with an unknown compound. The "N" qualifier was changed to a "J" qualifier in the data validation summary table. The laboratory has been asked to revise the non-target forms.

No other problems were found with the reported results of any of the samples of this delivery group.

FOOTNOTES FOR THE ORGANIC TARGET ANALYTE LIST

BLANK QUALIFIERS

1. The reported compound was less than 5 times (10 times for the common EPA contaminants) the value of the method (prep) blank. The presence of this compound in the sample has been negated.

SUMMARY OF THE ANALYTICAL DATA VALIDATION NYSDEC LAKA

Water TAL Inorganic Analyses Samples Received: February 10th through 13th, 1997

LAWLER, MATUSKY & SKELLY ENGINEERS LLP

APR 1 3 1998

n -- * 32 Andous Waste Section

Water samples were received for TAL metals analyses by NYS DEC ASP protocols. A complete analytical validation was performed based upon the following parameters:

- * Data Completeness
- * Holding Times
- * Calibration Verification
 - CRDL Standard
- * Laboratory Control Sample
 - Serial Dilutions
- * Calibration Blanks
 - Field Blanks
 - Preparation Blanks
 - Matrix Spike
 - Duplicate Analyses
- * ICP Interference Check Sample
- * Detection Limit Results
- * Linear Range
 - Furnace Atomic Absorption Results
 - Sample Results

Data Validation Summary

The concentration of chromium in the method blank (10.5 ug/l) was just above the 10 ug/l CRDL. The NYS DEC ASP quality assurance manual states that "all samples associated with the blank with the analyte's concentration less than 10x the blank concentration and above the CRDL, must be redigested and reanalyzed for that analyte". This was not done in the case of chromium. All of the chromium concentrations less than 100 ug/l were flagged with the "R" qualifier and footnoted with #1 in the data validation summary table.

The problems with the recoveries of the CRDL standards, serial dilutions and matrix duplicates should be noted by all end users of the data. These are discussed in detail below.

No other problems were found which would affect the end use of the data.

Nancy J. Potak April 9, 1998

^{* -} Indicates that all criteria were met for this parameter.

Holding Times

All samples were analyzed within the required holding times.

CRDL Standards

The recoveries of all CRDL standards in the first set were within the 80% to 120% quality assurance limits with the following exceptions in the second of the two ICP runs:

	Initial	Final
<u>Analyte</u>	% Recovery	% Recovery
Chromium	(ok)	134%
Zinc	(ok)	76%

Some of the low concentrations chromium may have been overestimated. The chromium data for these samples were flagged with the "J" qualifier and footnoted with #21 in the data validation summary table.

Some of the low concentrations zinc may have been underestimated. The zinc data for these samples were flagged with the "J" qualifier and footnoted with #21 in the data validation summary table.

Initial and Continuing Calibrations

No problems were detected with any of the calibrations associated with this sample delivery group.

Preparation Blank

The concentration of chromium in the method blank (10.5 ug/l) was just above the 10 ug/l CRDL. The NYS DEC ASP quality assurance manual states that "all samples associated with the blank with the analyte's concentration less than 10x the blank concentration and above the CRDL, must be redigested and reanalyzed for that analyte".

This was not done in the case of chromium. All of the chromium concentrations less than 100 ug/l were flagged with the "R" qualifier and footnoted with #1 in the data validation summary table.

Several other analytes were found in the preparation blanks at concentrations between the absolute value of CRDL and instrument detection limit. The data were not required to be qualified for these low concentrations.

Calibration Blanks

No compounds were detected in any of the calibration blanks associated with the analyses of these samples at concentrations above the CRDL.

Field Blank

Only a low concentration of iron (725 ug/l) was detected in the field blank at a concentration above the CRDL. The iron concentrations in the samples were too high to be affected by this concentration.

ICP Interference Check Sample

No problems were detected with the reported ICP Interference Check Sample recoveries.

Matrix Spike Recovery

Sample MW-201 (Lab. #: 9801459) of this sample delivery group was used for the total matrix spike for the full inorganic TCL analyte list. All recoveries were within the acceptable limits.

The initial analytical report submitted by the laboratory had flagged all of the ICP analytes in FORM I's with the "N" qualifier. This was a typographical error and corrected copies of the forms were received from the laboratory.

Duplicate Analysis

Sample MW-201 (Lab. #: 9801459) of sample delivery group 6831 was used for the total matrix duplicate for the full inorganic TCL analyte list. All recoveries which could be calculated were within the acceptable quality assurance limits with the following exception:

Analyte	RPD	Qualifier
Zinc	75%	43

The data for this analyte should be considered to be highly estimated values. The zinc data was flagged with the "J" qualifier and footnoted with #43 in the data validation summary table.

Laboratory Control Sample

No problems were detected with the recoveries of the water LCS standard.

Serial Dilutions

Sample MW-2 (Lab. #: 9717207) of sample delivery group 6829 was used for the total serial dilution analysis for the full inorganic TCL analyte list. All recoveries which could be calculated were within the acceptable quality assurance limits with the following exceptions:

Analyte	% Difference
Aluminum	26%
Barium	27%
Calcium	29%
Iron	28%
Magnesium	31%
Manganese	29%
Sodium	28%

The data for these analytes were flagged with the "J" qualifier and footnoted with #51 in the data validation summary table. The concentrations reported should be considered to be estimated values.

Instrument Detection Limit

No problems were found with the reported instrument detection limits.

ICP Linear Ranges

No problems were detected with the linear ranges. The reported concentrations of all samples in this delivery group were within their linear range for each analyte.

Furnace Analyses

Some of the thallium raw data was out of order (page I-259).

It appeared that some of the "W" qualifiers may have been omitted by the laboratory. These do not significantly affect the end use of the data.

Mercury Analyses

No problems were found with the mercury analyses.

Cyanide Analyses

No problems were found with the cyanide analyses

Sample Results

Aside from those mentioned above, no other problems were detected with any of the samples.

Water TAL Inorganic Analyses

FOOTNOTES FOR THE INORGANIC TARGET ANALYTE LIST

BLANK QUALIFIERS

- 1. The value reported for the preparation blank is either greater than the CRDL when the IDL is less than or equal to the CRDL, or less than two times the IDL when the IDL is greater than the CRDL. All data greater than the CRDL concentration but less than ten times the preparation blank value are rejected (This footnote may also be applied to preparation blanks with concentrations less than the CRDL if low concentrations of TCL analytes could influence the end use of the data).
- 3. The inorganic value reported was greater than 10 times the value in the method (prep) blank and is considered to be "real" (J).
- 4. This analyte was qualified due to the negative value of the prep blank being greater than the absolute value of the CRDL. All associated sample results less than ten times the CRDL are rejected.
- 5. The value reported for the field blank is either greater than the CRDL when the IDL is less than or equal to the CRDL, or less than two times the IDL when the IDL is greater than the CRDL. All data greater than the CRDL concentration but less than five times the field blank value are negated. (This footnote may also be applied to preparation blanks with concentrations less than the CRDL if low concentrations of TCL analytes could influence the end use of the data.
- 6. The inorganic value reported was greater than 10 times the value in the method (prep) blank and is considered to be "real" (J).
- 8. This analyte was qualified due to the negative value of the calibration blank.
- 9. The inorganic value reported was less than 10 times the value in a calibration blank and the concentration in the calibration blank was greater than the CRDL. The reported value was negated due to probable contamination.
- 11. The inorganic value reported was greater than 10 times the value in a calibration blank and is considered "real" (J).
- 12. The result of this sample was qualified due to problem with a blank which was not included in the above footnotes. Refer to the text for discussion.
- 13. The result of this sample was rejected due to a severe problem with the blank which was not included in the above footnotes. Refer to the text for discussion.

CALIBRATION REQUIREMENTS

- 15. The calibration used for this analyte could not be followed. All results should be considered tentative until the discrepancy has been resolved.
- 16. The CLP calibration requirements were not followed for this analyte. The significance of this is discussed in the text (J/R).
- 17. The mid-range cyanide standard was not distilled. All results should be considered estimates (J).

18. The recovery of the initial or continuing calibration standard was outside of the required limit. The analyses should have been terminated and the instrument recalibrated. All data associated with this standard should be considered to be estimated values. See text.

CRDL STANDARD RECOVERIES

- 20. An **incorrect concentration** of CRDL standard was used for this analysis. Refer to the text for the significance of this on the data. Sample data was only qualified when the concentration was within the affected range.
- 21. The recovery of the CRDL standard was < 80%, but > 50% or between 121% and 150%. All low concentrations of analytes are considered estimated. Sample data was only qualified when the concentration was within the affected ranges. Non-detects were not qualified when the analyte was undetected and the CRDL recovery was between 121% and 150%.
- 22. The recovery of the CRDL standard was **less than 50%**. All values for low concentrations of this analyte are highly qualified. Associated data would be rejected according to the EPA HW-2 data validation guidelines if the sample concentration was within the affected ranges of the CRDL concentration (A.1.9.3.3).
- 23. The recovery of the CRDL standard was **greater than 150%** (this footnote is not used if the analyte was not detected). Associated data would be rejected according to the EPA HW-2 data validation guidelines if the sample concentration was within the affected range. (A.1.9.3.3).

SPIKE RECOVERIES

- 30. The **CLP required spike concentration was not added** to this sample. Refer to the text for discussion of the effect on the usability of the data.
- 31. The recovery of the aqueous predigestion spike was between 30% and 75%. The results were greater than the IDL. Significant matrix interference may be present. All samples associated with this quality assurance sample have been flagged with the "N" qualifier. The matrix interference associated with them may not be the same as that of the sample chosen for the matrix spike (J).
- 32. The recovery of the **aqueous** predigestion spike was less than 30%. Significant problems were found with matrix interference. All samples associated with this quality assurance sample have been flagged with the "N" qualifier. The data are unusable. The matrix interference associated with them may not be the same as that of the sample chosen for the matrix spike (R). Associated data would be **rejected** according to the EPA HW-2 data validation guidelines (A.1.9.7.4).
- 33. The recovery of the **aqueous** predigestion spike was **greater than 125% and less than 150%**, and the sample results were greater than the IDL. This indicates that matrix interference may be present. All samples associated with this quality assurance sample have been flagged with the "N" qualifier. The matrix interference associated with them may not be the same as that of the sample chosen for the matrix spike.
- 34. The recovery of the **aqueous** predigestion spike was **greater than 150%** and the sample results were greater than the IDL. This indicates that severe matrix interference may be present. All samples associated with this quality assurance sample have been

flagged with the "N" qualifier. The matrix interference associated with them may not be the same as that of the sample chosen for the matrix spike. Associated data would be rejected according to the EPA HW-2 data validation guidelines (A.1.9.7.4).

- 35. The recovery of the **soil** predigestion spike was **between 10% and 74%**. Significant matrix interference may be present. All samples associated with this quality assurance sample have been flagged with the "N" qualifier. The matrix interference associated with them may not be the same as that of the sample chosen for the matrix spike (J).
- 36. The recovery of the **soil** predigestion spike was **less than 10%**. Significant problems were found with matrix interference. All samples associated with this quality assurance sample have been flagged with the "N" qualifier. The data are unusable. The matrix interference associated with them may not be the same as that of the sample chosen for the matrix spike (R). Associated data would be **rejected** according to the EPA HW-2 data validation guidelines (A.1.9.7.5).
- 37. The recovery of the soil predigestion spike was between 126% and 200%, and the sample results were greater than the IDL. This indicates that matrix interference may be present. All samples associated with this quality assurance sample have been flagged with the "N" qualifier. The matrix interference associated with them may not be the same as that of the sample chosen for the matrix spike.
- 38. The recovery of the **soil** predigestion spike was **greater than 200%** and the sample results were greater than the IDL. This indicates that severe matrix interference may be present. All samples associated with this quality assurance sample have been flagged with the "N" qualifier. The matrix interference associated with them may not be the same as that of the sample chosen for the matrix spike. Associated data would be **rejected** according to the EPA HW-2 data validation guidelines (A.1.9.7.4).
- 39. The required post digestion spike was not analyzed for this element.
- 40. The recovery of the post digestion spike was less than 30%. Severe matrix interference is present.
- 41. Significant discrepancies exist between the recoveries of the predigestion and post digestion spikes. Refer to the text for a discussion of the impact of this on the data.
- 42. Spike or duplicate data was not included for this analyte.

DUPLICATE ANALYSES

- 43. The relative percent difference was greater than 50% for waters, or greater than 100% for soils (J).
- 44. The RPD data was incorrectly reported by the laboratory.
- 45. The RPD was greater than the 20% quality assurance limit, but less than 50% for water samples and less than 100% for soil samples.

LABORATORY CONTROL SAMPLE

46. The recovery of the LCS was less than 50%. The data would be rejected according to the EPA data validation guidelines (HW-2, A.1.19.3).

SERIAL DILUTION

- 47. A serial dilution was not analyzed for the samples of this delivery group. All concentrations greater than 10X the IDLs or greater than the CRDL when 10X the IDL is less than the CRDL.
- 48. The laboratory failed to flag this analyte with the "E" qualifier to denote that the serial dilution results did not meet the QC limit.
- 49. The percent difference of the serial dilution replicates was greater than 100% and the sample concentration was greater than 10X the CRDL. This data would be rejected according to EPA data validation guidelines (HW-2, A.1.20.4).
- 50. The field blank was used for the analysis of the serial dilution. All ICP data greater than 10X the IDL were flagged with the "J" qualifier.
- 51. The percent difference of the serial dilution for this analyte was greater than 10%, but less than 100%. The data for this analyte should be considered to be an estimated value.

SAMPLE ANALYSES

- 52. The value reported in the raw data has a significant negative drift which could affect the usability of low concentrations of this analyte. All data for low concentrations of this analyte should be considered to be estimated.
- 53. The analyte has been analyzed by a method which is not routinely used in this concentration range. Refer to the text for a discussion of any impact this may have on the usability of the data.
- 54. The results for this analyte have been qualified due to the nonconformance with the required holding time limitations.
- 55. The data for this analyte has been rejected. Refer to the text for discussion.
- 56. This sample was analyzed for dissolved metals. A dissolved matrix spike, serial dilution and duplicate were not performed. The quality assurance information for these analyses from the total metal data may not apply. Only those footnotes which concern the calibration quality assurance were noted for these samples.
- 57. The reported detection limit could not be confirmed from the initial calibration used for this analysis. The data was reported in the basis of the concentration of the lowest standard used in the initial calibration.
- 58. Raw data for this analysis was not found in the report. The data should be considered to be tentative until this is reviewed.
- 59. The laboratory flagged the data with a qualifier that did not apply to this sample matrix. The qualifier was removed in the data validation summary table. The data was flagged with the "J" qualifier to indicate that it was not possible to determine if any matrix interference would affect the end use of the data.

60. The raw data included in the report could not be followed. The results of this analysis should be considered tentative until the discrepancy has been resolved.

FURNACE ANALYSES

- 61. The duplicate injections are outside of the 20% RSD limits and the sample has not been rerun once was required (J).
- 62. The duplicate injections were reanalyzed and the RPD was still less than 20% (J).
- 63. The results of the analyte are greater than the IDL, but the recovery of the post digestion spike is less than 40%.
- **64**. The recovery of the post digestion spike is between 10% and 40%. The results of the sample are less than the IDL (UJ).
- 65. The recovery of the post digestion spike is less than 10% and the sample results are less than the IDL (R).
- 66. The sample absorbance is less than 50% of the post digestion spike absorbance, and greater than the IDL, and the post digestion spike is outside of the 85% 115% limits.
- 67. The sample absorbance is less than 50% of the post digestion spike absorbance, and less than the IDL, and the post digestion spike is outside of the 85% 115% limits.
- 68. The method of standard additions was required, but not performed (J).
- 69. The sample was analyzed by standard additions, but the required spiking concentrations were not used. (J).
- 70. The correlation coefficient of the method of standard addition was less than 0.990. The data for this sample would be technically rejected according to the EPA's data validation guidelines (HW-2, 1/92, A.1.22.2). The data should be examined in terms of the specific data quality objectives of the site. The results may be usable to estimate the degree of contamination at the site. The correlation coefficient is discussed in the text.
- 71. The analyses were not performed according to CLP methodology. Extensive problems were found and the data should not be used (See text).
- 72. The %RSD for the two ICP duplicates was greater than 50%. The results should be considered to be highly estimated.
- 73. The results of this analyte were qualified because the linear regression of the initial calibration was less than 0.995.
- 74. This sample was analyzed by furnace, but it was not analyzed in duplicate and a post digestion spike was not analyzed. The data for this analyte is rejected according to Section A.1.21.1 of the HW-2 EPA data validation protocols.

LINEAR RANGE

75. The data was reported from a concentration greater than the linear range.

PERCENT SOLIDS

80. <u>All</u> data for this sample is qualified due to the very high moisture content. The percent solids for this sample were between 10% and 50%.

ICP INTERFERENCE CHECK SAMPLE

81. The data for this analyte were rejected because its recovery in the ICP Interference Check Sample (solution AB) was less than 50%.

DATA USEABILITY REPORT

This useability report covers the analytical results, submitted by Accredited Laboratories, Inc. (Accredited), for the field sampling investigation, conducted by Lawler, Matusky & Skelly Engineers LLP (LMS) in September 1998 at the Laka site. The analytical report submitted by Accredited, sample designation group (SDG) 1781, 1933, and 1696 was validated by Nancy J. Potak's Data Validation. LMS reviewed the data validator's final report and assessed the analytical data against the project data quality objectives (DQOs) in preparation of this report. Where resulting quality control (QC) data did not fall within protocol requirements the reported data in the Focused Remedial Investigation Report (FRI) have been appropriately qualified. The data submitted by Accredited are useable to approximate levels of select environmental contaminants in samples collected as part of the Laka investigation.

A total of two (2) subsurface soil samples and three (3) groundwater probe samples were collected as part of the Laka investigation and analyzed for contract laboratory program (CLP) target compound list (TCL) volatile organic compounds. All of the analyses were conducted in accordance with the most recent version of the New York State Department of Environmental Conservation (NYSDEC) Analytical Services Protocol (ASP).

Those instances where the reported data were noncompliant are described in the data validator's report. This report presents a discussion of any impacts that noncompliant data and any other issues raised by the validator may have on the useability of the reported results.

Volatile Organic Compound Analysis

Soil Samples

The soil samples submitted to Accredited were analyzed for TCL VOCs in accordance with NYSDEC ASP CLP Method 95-1. A total of two (2) subsurface soil samples were collected from the same site location and identical depths during separate sampling events. The first sample was collected on 11 September 1998 and the second sample was collected on 30 September 1998.

Where reported concentrations may have been affected by QC failures the data useability is discussed below:

- 1. The sample collected on 11 September 1998 was received by the Laboratory on 14 September 1998. The laboratory log sheet indicated the temperature of the sample was 72°F (22°C) upon receipt. As a result, all data associated with sample B(16-20) collected on 11 September 1998 are considered estimated and values reported may be significantly underestimated (biased low).
- 2. Methylene chloride was detected in the method blanks associated with both soil sampling events at a level which was comparable to detections in field samples. The presence of methylene chloride in the samples, therefore, is not considered to be representative of site conditions and the validator rejected all detections of the compound. Methylene chloride was removed, therefore, as a detected compound in the final data summary table prepared by LMS.
- 3. Instrument detection limits (IDLs) were performed four months beyond the required six month limit which is outside of the NYSDEC ASP requirement of 6 months. Data useability is unaffected and no qualification is required.
- 4. A site specific matrix spike (MS) and matrix spike duplicate (MSD) was taken with the soil sample collected on 30 September 1998. The relative percent difference (RPD) calculation for trichloroethylene at 39% exceeded the acceptable quality control limit of 24%. All other recoveries and RPDs for this sample were within the acceptable quality control. Data useability is unaffected and no qualification is indicated.
- 5. The analytical report for the soil sample collected on 11 September 1998 was not issued according to standard NYSDEC ASP protocols. Data were validated according to standard NYSDEC ASP protocol. No additional data qualification is necessary and data useability is unaffected.

Groundwater Probe Samples

A total of three (3) groundwater probe samples were collected on 18 September 1998 and submitted to Accredited were analyzed for TCL VOCs in accordance with NYSDEC ASP CLP Method 95-1. Where reported concentrations may have been affected by QC failures the data useability is discussed below:

- 1. All samples collected were analyzed twelve (12) days outside of the NYSDEC ASP holding time. In addition, based on LMS' review of the data package, the laboratory log sheet indicated the temperature of the samples were 70°F (21°C) upon receipt. As a result, all groundwater probe sample results are considered estimated and values reported may be significantly underestimated (biased low).
- 2. Methylene chloride was detected in the associated method blank at a level which was comparable to detections in field samples. The presence of methylene chloride in the samples, therefore, is not considered to be representative of site conditions and the validator rejected all detections of the compound. Methylene chloride was removed, therefore, as a detected compound in the final data summary table prepared by LMS.
- 3. Acetone was detected in the holding blank at a concentration which was less than five times the concentrations detected in samples FLGP-W1(62-63 ft) and FLGP-W1 (72-73 ft). The presence of acetone in these samples, therefore, is not considered to be representative of site conditions and the validator rejected detections of the compound in the affected samples. Acetone was removed, therefore, as a detected compound in these samples in the final data summary table prepared by LMS. The acetone concentration in sample FLGP-W1 (92-93) was sufficiently high as not to have been affected by the blank contamination, therefore, no additional qualification for this sample is required.

SUMMARY OF THE ANALYTICAL DATA VALIDATION For The Former LAKA Site

Soil Volatile Organic Analyses

Sample Received: September 14, 1998

Sample Delivery Group: 1696 **Laboratory Reference Number:**

> B(16-20) B(16-20)DL

9810381 9810381DL

One soil sample was received for analyses of the volatile organic TCL analyte list by NYS DEC ASP protocols. A complete analytical validation was performed based upon the following parameters:

- * Data Completeness
- * GC/MS Tuning
- * Holding Times
 - Calibrations
 - Laboratory Blanks
 - Field Blanks
 - Trip Blanks
 - Holding Blank
- * System Monitoring Compound Recoveries
- * Internal Standard Recoveries
 - Matrix Spike / Matrix Spike Duplicate
- * Blank Spike
- * Compound Identification
- * Compound Quantitation
 - Method Detection Limit

DATA VALIDATION SUMMARY

The sample was collected on 9/11, but was not received by the laboratory until 9/14. The laboratory's case narrative notes that the temperature upon receipt was 72 degrees F. The volatile organic data for this sample may have been significantly underestimated. All of the data were flagged with the "J" qualifier and the "See Text" notation.

The analytical report was not issued in a NYS DEC ASP format. None of the standard ASP forms were used and compounds in addition to those of the standard target compound list were present on the laboratory's summary forms.

The data were validated according to standard NYS DEC ASP protocols.

^{* -} Indicates that all criteria were met for this parameter.

The soil sample was reanalyzed at a 20X dilution due to a very high concentration of trichloroethene (3,500 ug/kg). When the sample was reanalyzed it was mislabeled in Form V as 9810281DL instead of 9810381.

It appears that 0.25 grams of sample was analyzed in the dilution. The standard NYS DEC midlevel extraction did not appear to have been used.

The percent difference of carbon disulfide in both continuing calibrations were 210%. Carbon disulfide was not detected in this sample, but the data for this compound was technically rejected due to the very poor continuing calibration criteria.

Trip and field blanks were not included with this sample.

Non-target compounds were not analyzed with these samples.

The instrument detection limit analyses were performed 4 months beyond the required six month limit.

No other problems were found with the analyses of these samples which would affect the end use of the data.

Nancy J. Potak October 24, 1988

Holding Times

All samples were analyzed within the 10 day NYS DEC ASP required holding time.

Tunes

No problems were found with any of the tunes of this sample delivery group.

System Monitoring Compound Recoveries

All system monitoring compound recoveries were within the NYS DEC's ASP quality assurance limits.

Calibrations

No problems were detected with one the initial calibration of this sample delivery group.

The percent difference of carbon disulfide in both continuing calibrations were 210%. Carbon disulfide was not detected in this sample, but the data for this compound was technically rejected due to the very poor continuing calibration criteria.

The percent difference of xylene (33% & 30%) was also above the 25% quality assurance limit in both continuing calibrations. Xylene was not detected in any of the samples of this delivery group. The data for xylene were flagged with the "J" qualifier and footnoted with #15 in the data validation summary table.

No other problems were detected with any of the initial or continuing calibrations.

Matrix Spike / Matrix Spike Duplicate

Sample 9810360 of another sample delivery group was used for the matrix spike and matrix spike duplicate. All recoveries and RPDs were within the acceptable quality control limits. It is not known if the matrix of this sample is similar to sample B(16-20). Data for this matrix spike and matrix spike duplicate were not reviewed during this validation.

Blank Spike

No problems were found with the recoveries of the blank spike.

Method Blanks

Low concentrations of methylene chloride (2J ug/kg) were detected on both method blanks. Methylene chloride was negated from both samples according to standard EPA data validation procedures.

Trip Blanks

A trip blank was not included with this sample delivery group.

Holding Blank

A holding blank was not analyzed with this sample delivery group.

Field Blank

A field blank was not associated with this sample delivery group.

Internal Standard Areas and Retention Times

No problems were found with the recoveries or retention times in any of the internal standards associated with the samples of this delivery group.

Instrument Detection Limits

The instrument detection limit analyses were performed 4 months beyond the required six month limit.

No other problems were detected with the laboratory's reported instrument detection limits.

Sample Results

The sample was collected on 9/11, but was not received by the laboratory until 9/14. The laboratory's case narrative notes that the temperature upon receipt was 72 degrees F. The volatile organic data for this sample may have been significantly underestimated. All of the data were flagged with the "J" qualifier and the "See Text" notation.

It appears that 0.25 grams of sample was analyzed in the dilution. The standard NYS DEC midlevel extraction did not appear to have been used.

Non-target compounds were not analyzed with these samples.

No other problems were found with the reported results of any of the samples of this delivery group.

SUMMARY OF THE ANALYTICAL DATA VALIDATION For Former LAKA Site

Soil Volatile Organic Analyses - Method 95-1 Sample Received: October 1, 1998 Sample Delivery Group: 1933 Laboratory Reference Number:

> 16-20 9811260 16-20MS 9811260MS 16-20MSD 9811260MSD

One soil sample was received for analyses of the volatile organic TCL analyte list by NYS DEC ASP protocols. A complete analytical validation was performed based upon the following parameters:

- * Data Completeness
- * GC/MS Tuning
 - Holding Times
 - Calibrations
 - Laboratory Blanks
 - Field Blanks
- * Holding Blank
 - Trip Blanks
- * System Monitoring Compound Recoveries
- * Internal Standard Recoveries
- * Matrix Spike / Matrix Spike Duplicate
- * Blank Spike
- * Compound Identification
- * Compound Quantitation
 - Method Detection Limit
- * Indicates that all criteria were met for this parameter.

LAWLER, MATUSKY & SKELLY ENGINEERS LLP

NOV 0 2 1998

For Hazardous Waste Section

DATA VALIDATION SUMMARY

The instrument detection limit analyses were performed 4 months beyond the required six month limit.

Trip and field blanks were not included with this sample.

The high RPD of trichloroethene (33%) in the matrix spike should be noted.

No other problems were found with the analyses of these samples which would affect the end use of the data.

Nancy J. Potak October 29, 1988

Holding Times

All samples were analyzed within the 10 day NYS DEC ASP holding time.

Tunes

The FORM Vs were not found in the correct order in the report (page 62)

The EPA tune criteria were reported on FORM V instead of those of the NYS DEC ASP program. The data were reviewed in terms of the NYS DEC ASP criteria.

No problems were found with any of the tunes of this sample delivery group.

System Monitoring Compound Recoveries

All system monitoring compound recoveries were within the NYS DEC's ASP quality assurance limits.

Calibrations

The percent RSD of vinyl chloride (24%) was above the 20.5% quality assurance limit. The data for this compound was flagged with the "J" qualifier and footnoted with #15 in the data validation summary table. This compound was not detected in the sample.

Section D 9.3.5.4 of the NYS DEC ASP Manual states that up to 2 compounds may fail the criteria and still meet the minimum response factor and %RSD requirements. These compounds must have a minimum RRF greater or equal to 0.010 and the %RSD must be less than or equal to 40%. This requirement was satisfied in all of the calibrations of this sample delivery group.

Matrix Spike / Matrix Spike Duplicate

Sample 16-20 (Lab. #: 9811260) of this sample delivery group was used for the matrix spike and matrix spike duplicate. All recoveries and RPDs were within the acceptable quality control limits with the one exception of the RPD of trichloroethene (39%). This was above the 24% quality assurance limit for this analyte.

Blank Spike

No problems were found with the recoveries of the blank spike.

Method Blanks

A low concentration of methylene chloride (2J ug/l) and a non-target compound were detected in the method blank. Methylene chloride was negated according to standard EPA data validation protocols. The non-target compound was not detected in the sample.

Holding Blank

No compounds were detected in the holding blank associated with the analyses of these samples.

Data for an additional holding blank was also included in the analytical report. The data for this blank was not reviewed during the validation.

Trip Blanks

A trip blank was not included with this sample delivery group.

Field Blank

A field blank was not associated with this sample delivery group.

Internal Standard Areas and Retention Times

No problems were found with the recoveries or retention times in any of the internal standards associated with the samples of this delivery group.

Instrument Detection Limits

The instrument detection limit analyses were performed 4 months beyond the required six month limit.

No other problems were detected with the laboratory's reported instrument detection limits.

Sample Results

Many of the non-target unknown hydrocarbons in the sample were flagged with the "N" qualifier by the laboratory. The "J" qualifier should have been used. This was amended in the data validation summary table.

No other problems were found with the reported results of the sample of this delivery group.

SUMMARY OF THE ANALYTICAL DATA VALIDATION For Former LAKA Site

LAWLER, MATUSKY & SKELLY ENGINEERS LLP

Water Volatile Organic Analyses - Method 95-1 Samples Received: September 21, 1998

NOV 0 2 1998

Sample Delivery Group: 1781 Laboratory Reference Number:

For Hazardous Waste Section

W1 92-93	9810777
W1 92-93DL	9810777DL
W1 72-73	9810778
W1 72-73MS	9810778MS
W1 72-73MSD	9810778MSD
W1 62-63	8710779

Water samples were received for analyses of the volatile organic TCL analyte list by NYS DEC ASP protocols. A complete analytical validation was performed based upon the following parameters:

- * Data Completeness
- * GC/MS Tuning
 - Holding Times
- * Calibrations
 - Laboratory Blanks
 - Field Blanks
 - Holding Blank
 - Trip Blanks
- * System Monitoring Compound Recoveries
- * Internal Standard Recoveries
- * Matrix Spike / Matrix Spike Duplicate
- * Blank Spike
- * Compound Identification
- * Compound Quantitation
 - Method Detection Limit

^{* -} Indicates that all criteria were met for this parameter.

DATA VALIDATION SUMMARY

The samples of this delivery group were analyzed 12 days beyond the 10 day NYS DEC ASP holding time. The data reported for these samples may be significantly underestimated and low concentrations of some volatile compounds may have been overlooked. The laboratory did not note this problem in their case narrative.

Sample W1 92-93 was reanalyzed at a 5x dilution due to a high concentration of acetone (210 ug/l)

Trip and field blanks were not included with this sample.

The instrument detection limit analyses were performed 4 months beyond the required six month limit.

No other problems were found with the analyses of these samples which would affect the end use of the data.

Nancy J. Potak October 29, 1988

Holding Times

The samples of this delivery group were analyzed 12 days beyond the 10 day NYS DEC ASP holding time. The data reported for these samples may be significantly underestimated and low concentrations of some volatile compounds may have been overlooked.

Tunes

The FORM Vs were not found in the correct order in the report (page 115)

The EPA tune criteria were reported on FORM V instead of those of the NYS DEC ASP program. The data were reviewed in terms of the NYS DEC ASP criteria.

No problems were found with any of the tunes of this sample delivery group.

System Monitoring Compound Recoveries

All system monitoring compound recoveries were within the NYS DEC's ASP quality assurance limits.

Calibrations

No problems were detected with any of the initial or continuing calibrations.

Matrix Spike / Matrix Spike Duplicate

Sample W1 72-73 (Lab. #: 810778) of this sample delivery group was used for the matrix spike and matrix spike duplicate. All recoveries and RPDs were within the acceptable quality control limits.

Blank Spike

No problems were found with the recoveries of the blank spike.

Method Blanks

A low concentration of methylene chloride (2J ug/l) and a non-target compound were detected in the method blank associated with the initial analyses of these samples. Both of these compounds were negated according to standard EPA data validation protocols when ever they were detected in a sample.

The non-target compound was also detected in samples W1 72-73 and W1 62-63, but was not flagged with the "B" qualifier by the laboratory. This was added in the data validation summary table.

Methylene chloride (15 ug/l) and acetone (5J ug/l) were both found in the method blank associated with the diluted analysis of sample W1 92-93. The methylene chloride in the diluted sample was negated, but the acetone was only qualified due to its high concentration in the sample (42 ug/l prior to correction for dilution). The concentration of acetone in the method blank did not affect the end use of the data for this compound in the sample.

Holding Blank

Acetone was detected in the holding blank at a concentration of 13 ug/l. This was footnoted with #2 and negated in all samples with the one exception of sample W1 92-93. The acetone concentration in this sample was too high to be affected by the acetone concentration in the holding blank.

Trip Blanks

A trip blank was not included with this sample delivery group.

Field Blank

A field blank was not associated with this sample delivery group.

Internal Standard Areas and Retention Times

The instrument detection limit analyses were performed 4 months beyond the required six month limit.

No other problems were found with the recoveries or retention times in any of the internal standards associated with the samples of this delivery group.

Instrument Detection Limits

No problems were detected with the laboratory's reported instrument detection limits.

Sample Results

Sample W1 92-93 was reanalyzed at a 5x dilution due to a high concentration of acetone (210 ug/l)

The non-target unknown hydrocarbon in sample W1 72-73 was flagged with the "N" qualifier by the laboratory. The "J" qualifier should have been used. This was added in the data validation summary table. This compound was also detected in the method blank and negated according to standard EPA data validation protocols.

No other problems were found with the reported results of any of the samples of this delivery group.

LMS One Blue Hill Plaza Pearl River, NY 10965 For Hazardous Waste Section

Project: NYSDEC LAKA (650-272)

Accredited Laboratories Case No.: 8342 Date Received: 02/10/98,02/11/98,02/12/98,02/13/98

> Laboratory Field ID Sample # TB 5/6 9801515

Accredited Laboratories, Inc. New Jersey Certification Number 12007. This data has been reviewed and accepted by:

Yun-shen Lee, Ph.D.3/57 Technical Director

SDG NARRATIVE

Accredited Labs received 20 aqueous samples (Project: NYSDEC LAKA RI (650-272); ALI Case #8342) from LMS Engineers on 2/10,11,12,13/98 for the analyses of Volatile Organics, TAL Metals and Cyanide. The Volatile analysis was based on NYSDEC-ASP 95-1, the Inorganic analysis was based on NYSDEC-ASP CLP Inorganic method and Cyanide was based on 335.2 CLP-M.

All analyses were performed within the required holding time.

"I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package has been authorized by the Laboratory Manager or his designee, as verified by the following signature."

Yun-shen Lee, Ph.D. 3/5/98 Technical Director

SDG NARRATIVE

Accredited Labs received 3 soil samples (Project: LAKA RI/FS; ALI Case #7973) from LMS Engineers on 01/06/98 for the analyses of Volatile Organics.

All analyses were performed within the required holding time.

All soil analyses were reported on a dry weight basis.

"I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package has been authorized by the Laboratory Manager or his designee, as verified by the following signature."

METHODOLOGY SUMMARY

Volatile Organics: EPA-CLP-SOW (Document Number OLM03.1)

Soil/Sediment Samples

a. Low level:

An inert gas is purged through a mixture containing 5g of sample and reagent water at an elevated temperature. The volatile organics are efficiently transferred from aqueous phase to the vapor phase and then trapped onto a sorbent column. When purging is completed, the sorbent column is heated and backflushed with the inert gas to desorb the volatile organics from the sorbent column to a GC column. The GC is temperature programmed to separate the volatile organics which are then detected and quantified with a mass spectrometer.

SDG NARRATIVE

Accredited Labs received 22 soil samples and 1 aqueous sample (Project: LAKA RI/FS; ALI Case #7987) from LMS Engineers on 1/07/98 for the analyses of Volatile Organics, TAL Metals and Total Cyanide.

All analyses were performed within the required holding time.

All soil analyses were reported on a dry weight basis.

In the Volatile Organic analyses, ALI samples #9800141, #9800143, #9800148, #9800150 and #9800151 have compounds whose concentration exceeds the calibration range of the instrument. The samples were diluted and re-analyzed and reported.

"I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package has been authorized by the Laboratory Manager or his designee, as verified by the following signature. "

METHODOLOGY SUMMARY

Volatile Organics: EPA-CLP-SOW (Document Number OLM03.1)

Water Samples

Volatile organic compounds are purged from a 5ml sample at ambient temperature by bubbling an inert gas through the aqueous sample. The volatile organics are efficiently transferred from aqueous phase to the vapor phase and then trapped onto a sorbent column. When purging is completed, the sorbent column is heated and backflushed with the inert gas to desorb the volatile organics from the sorbent column to a GC column. The GC is temperature programmed to separate the volatile organics which are then detected and quantified with a mass spectrometer.

Soil/Sediment Samples

a. Low level:

An inert gas is purged through a mixture containing 5g of sample and reagent water at an elevated temperature. The volatile organics are efficiently transferred from aqueous phase to the vapor phase and then trapped onto a sorbent column. When purging is completed, the sorbent column is heated and backflushed with the inert gas to desorb the volatile organics from the sorbent column to a GC column. The GC is temperature programmed to separate the volatile organics which are then detected and quantified with a mass spectrometer.

TAL Metals: EPA-CLP-SOW (Document Number ILM04.0)

Water Samples

a. Furnace AA Analysis:

A 100ml portion of sample is digested with nitric acid and 30% H_2O_2 on a hot plate for 2 hours at 95°C or until sample volume is reduced to between 25 and 50ml. The digested sample is cooled, filtered and volume-adjusted to 100ml with reagent water. The digestate is then analyzed by Graphite Furnace Atomic Absorption Spectroscopy.

b. ICP and Flame AA Analysis:

A 100ml portion of sample is digested with the mixed acids of nitric acid and hydrochloric acid on a hot plate for 2 hours at 95°C or until sample volume is reduced to between 25 and 50ml. The digested sample is cooled, filtered and volume-adjusted to 100ml with reagent water. The digestate is then analyzed by either Flame Atomic Absorption Spectroscopy or Inductively Coupled Plasma Spectroscopy.

c. Cold Vapor Technique for Mercury Analysis:

A 100ml portion of sample is digested with the mixed acids (sulfuric acid and nitric acid) and the oxidizing agents (potassium permanganate and potassium persulfate) in a water bath at 95°C. The excess potassium permanganate in the cooled digestate is reduced by adding the sodium chloride
hydroxylamine sulfate. The mercury in the digestate is

reduced to the elemental state and detected by Cold Vapor Atomic Absorption Spectroscopy.

Soil/Sediment Samples

A 1qm portion of sample is digested with nitric acid and hydrogen peroxide. The digestate is then refluxed with either nitric acid or hydrochloric acid. Diluted hydrochloric acid is used as the final reflux acid for the Furnace AA analysis of Sb, the Flame AA or ICP analysis of Al, Sb, Ba, Be, Ca, Cd, Cr, Co, Cu, Fe, Pb, Mg, Mn, Ni, K, Ag, Na, Tl, V and Zn. Nitric acid is employed as the final reflux acid for the Furnace AA analysis of As, Be, Cd, Cr, Co, Cu, Fe, Pb, Mn, Ni, Se, Ag, Tl, V and Zn. For the graphite furnace analysis, an aliquot of the digestate is spiked with modifier solution and is placed into the graphite furnace. aliquot is then slowly evaporated to dryness, charred and atomized. The absorption of the EDL radiation during atomization is proportional to the element concentration. For the flame AA, the digestate is aspirated and atomized in a flame. The absorption of the HCL radiation during atomization is proportional to the element concentration. The basis of ICAP method is the measurement of atomic emission by an optical spectroscope technique. The emission spectra are dispersed by a grating spectrometer and the intensities of the line are measured and processed by a computer system. mercury analysis, a 0.2qm portion of sample is digested with potassium permanganate and persulfate at acidic condition in a water bath at 95°C. The mercury in the sample is reduced to the elemental state and detected by the cold vapor technique in a closed system.

Total Cyanide: EPA-CLP-SOW (Document Number ILM03.0)

Water Samples

A 500ml portion of sample is placed into a cyanide distillation apparatus. Hydrogen cyanide gas is liberated from the aqueous solution upon addition of sulfuric acid, magnesium chloride solution and heat. The hydrogen cyanide gas is trapped in a scrubber containing sodium hydroxide solution. The color is formed when the reagents of chloramine-T and pyridine-barbifuric acid mixture is added into scrubber solution. The intensity of the color is measured spectrophotometrically and is proportional to the concentration of cyanide in the solution.

Soil/Sediment Samples

A 1-5gm portion of sample mixed with reagent water is placed into a cyanide distillation appartus. Hydrogen cyanide gas is liberated from the aqueous solution upon addition of sulfuric acid, magnesium chloride solution and heat. The hydrogen cyanide gas is trapped in a scrubber containing sodium hydroxide solution. The color is formed when the reagents of chloramine-T and pyridine-barbifuric acid mixture is added into scrubber solution. The intensity of the color is measured spectrophotometrically and is proportional to the concentration of cyanide in the solution.

SDG NARRATIVE

Accredited Labs received 11 soil samples (Project: LAKA RI; ALI Case #8007) from LMS Engineers on 1/08/98 for the analyses of Volatile Organics, TAL Metals and Total Cyanide.

All analyses were performed within the required holding time.

All soil analyses were reported on a dry weight basis.

"I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package has been authorized by the Laboratory Manager or his designee, as verified by the following signature."

#### METHODOLOGY SUMMARY

Volatile Organics: EPA-CLP-SOW (Document Number OLM03.1)

#### Soil/Sediment Samples

#### a. Low level:

An inert gas is purged through a mixture containing 5g of sample and reagent water at an elevated temperature. The volatile organics are efficiently transferred from aqueous phase to the vapor phase and then trapped onto a sorbent column. When purging is completed, the sorbent column is heated and backflushed with the inert gas to desorb the volatile organics from the sorbent column to a GC column. The GC is temperature programmed to separate the volatile organics which are then detected and quantified with a mass spectrometer.

TAL Metals: EPA-CLP-SOW (Document Number ILM04.0)

### Soil/Sediment Samples

A 1gm portion of sample is digested with nitric acid and hydrogen peroxide. The digestate is then refluxed with either nitric acid or hydrochloric acid. Diluted hydrochloric acid is used as the final reflux acid for the Furnace AA analysis of Sb, the Flame AA or ICP analysis of Al, Sb, Ba, Be, Ca, Cd, Cr, Co, Cu, Fe, Pb, Mg, Mn, Ni, K, Aq, Na, Tl, V and Zn. Nitric acid is employed as the final reflux acid for the Furnace AA analysis of As, Be, Cd, Cr, Co, Cu, Fe, Pb, Mn, Ni, Se, Ag, Tl, V and Zn. For the graph furnace analysis, an aliquot of the digestate is spiked with For the graphite modifier solution and is placed into the graphite furnace. aliquot is then slowly evaporated to dryness, charred and atomized. The absorption of the EDL radiation during atomization is proportional to the element concentration. For the flame AA, the digestate is aspirated and atomized in a flame. The absorption of the HCL radiation during atomization is proportional to the element concentration. The basis of ICAP method is the measurement of atomic emission by an optical spectroscope technique. The emission spectra are dispersed by a grating spectrometer and the intensities of the line are measured and processed by a computer system. mercury analysis, a 0.2gm portion of sample is digested with potassium permanganate and persulfate at acidic condition in a water bath at 95°C. The mercury in the sample is reduced to the elemental state and detected by the cold vapor technique in a closed system.

Total Cyanide: EPA-CLP-SOW (Document Number ILM03.0)

### Soil/Sediment Samples

37

A 1-5gm portion of sample mixed with reagent water is placed into a cyanide distillation appartus. Hydrogen cyanide gas is liberated from the aqueous solution upon addition of sulfuric acid, magnesium chloride solution and heat. The hydrogen cyanide gas is trapped in a scrubber containing sodium hydroxide solution. The color is formed when the reagents of chloramine-T and pyridine-barbifuric

acid mixture is added into scrubber solution. The intensity of the color is measured spectrophotometrically and is proportional to the concentration of cyanide in the solution.

SDG NARRATIVE

Accredited Labs received 2 sludge samples, 1 aqueous sample and 6 soil samples (Project: LAKA RI/FS (650-272);
ALI Case #8039) from LMS Engineers on 1/09/98 for the analyses of Volatile Organics, Base Neutral Acid Extractables, TAL Metals and Total Cyanide.

All analyses were performed within the required holding time.

All soil analyses were reported on a dry weight basis.

In the Volatile Organic analyses, the MDL's are slightly elevated due to the matrix interference for ALI samples #9800386 and #9800387.

"I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package has been authorized by the Laboratory Manager or his designee, as verified by the following signature."

Yun-shen Lee, Ph.D.

METHODOLOGY SUMMARY

Volatile Organics: EPA-CLP-SOW (Document Number OLM03.1)

Water Samples

Volatile organic compounds are purged from a 5ml sample at ambient temperature by bubbling an inert gas through the aqueous sample. The volatile organics are efficiently transferred from aqueous phase to the vapor phase and then trapped onto a sorbent column. When purging is completed, the sorbent column is heated and backflushed with the inert gas to desorb the volatile organics from the sorbent column to a GC column. The GC is temperature programmed to separate the volatile organics which are then detected and quantified with a mass spectrometer.

Soil/Sediment Samples

a. Low level:

An inert gas is purged through a mixture containing 5g of sample and reagent water at an elevated temperature. The volatile organics are efficiently transferred from aqueous phase to the vapor phase and then trapped onto a sorbent column. When purging is completed, the sorbent column is heated and backflushed with the inert gas to desorb the volatile organics from the sorbent column to a GC column. The GC is temperature programmed to separate the volatile organics which are then detected and quantified with a mass spectrometer.

Semi-volatile Organics: EPA-CLP-SOW (Document Number OLM03.1)

Water Samples

A one liter aliquot of sample is acidified to pH 2 and extracted with methylene chloride using a continuous liquid-liquid extractor. The methylene chloride extract is dried and concentrated to a volume of 1.0ml. The final sample extract is spiked with internal standards and analyzed by a GC/MS system.

Soil/Sediment Samples

a. Low level:

A 30gm portion of sample is mixed with anhydrous Na₂SO₄ and extracted with 1:1 methylene chloride/acetone using an ultrasonic probe. The extract is dried and concentrated. The concentrated extract is subjected to GPC cleanup and analyzed by a GC/MS system.

TAL Metals: EPA-CLP-SOW (Document Number ILM04.0)

Water Samples

a. Furnace AA Analysis:

A 100ml portion of sample is digested with nitric acid and 30% H_2O_2 on a hot plate for 2 hours at 95°C or until sample volume is reduced to between 25 and 50ml. The digested sample is

cooled, filtered and volume-adjusted to 100ml with reagent water. The digestate is then analyzed by Graphite Furnace Atomic Absorption Spectroscopy.

b. ICP and Flame AA Analysis:

A 100ml portion of sample is digested with the mixed acids of nitric acid and hydrochloric acid on a hot plate for 2 hours at 95°C or until sample volume is reduced to between 25 and 50ml. The digested sample is cooled, filtered and volume-adjusted to 100ml with reagent water. The digestate is then analyzed by either Flame Atomic Absorption Spectroscopy or Inductively Coupled Plasma Spectroscopy.

c. Cold Vapor Technique for Mercury Analysis:

A 100ml portion of sample is digested with the mixed acids (sulfuric acid and nitric acid) and the oxidizing agents (potassium permanganate and potassium persulfate) in a water bath at 95°C. The excess potassium permanganate in the cooled digestate is reduced by adding the sodium chloride-hydroxylamine sulfate. The mercury in the digestate is reduced to the elemental state and detected by Cold Vapor Atomic Absorption Spectroscopy.

Soil/Sediment Samples

A 1gm portion of sample is digested with nitric acid and hydrogen peroxide. The digestate is then refluxed with either nitric acid or hydrochloric acid. Diluted hydrochloric acid is used as the final reflux acid for the Furnace AA analysis of Sb, the Flame AA or ICP analysis of Al, Sb, Ba, Be, Ca, Cd, Cr, Co, Cu, Fe, Pb, Mg, Mn, Ni, K, Ag, Na, Tl, V and Zn. Nitric acid is employed as the final reflux acid for the Furnace AA analysis of As, Be, Cd, Cr, Co, Cu, Fe, Pb, Mn, Ni, Se, Ag, Tl, V and Zn. For the graphite furnace analysis, an aliquot of the digestate is spiked with modifier solution and is placed into the graphite furnace. aliquot is then slowly evaporated to dryness, charred and atomized. The absorption of the EDL radiation during atomization is proportional to the element concentration. For the flame AA, the digestate is aspirated and atomized in a flame. The absorption of the HCL radiation during atomization is proportional to the element concentration. The basis of ICAP method is the measurement of atomic emission by an optical spectroscope technique. The emission spectra are dispersed by a grating spectrometer and the intensities of the line are measured and processed by a computer system. mercury analysis, a 0.2gm portion of sample is digested with potassium permanganate and persulfate at acidic condition in a water bath at 95°C. The mercury in the sample is reduced to the elemental state and detected by the cold vapor technique in a closed system.

Total Cyanide: EPA-CLP-SOW (Document Number ILM03.0)

Water Samples

50

A 500ml portion of sample is placed into a cyanide distillation apparatus. Hydrogen cyanide gas is liberated from the aqueous solution upon addition of sulfuric acid, magnesium chloride solution and heat. The hydrogen cyanide gas is trapped in a scrubber containing sodium hydroxide solution. The color is formed

when the reagents of chloramine-T and pyridine-barbifuric acid mixture is added into scrubber solution. The intensity of the color is measured spectrophotometrically and is proportional to the concentration of cyanide in the solution.

Soil/Sediment Samples

A 1-5gm portion of sample mixed with reagent water is placed into a cyanide distillation appartus. Hydrogen cyanide gas is liberated from the aqueous solution upon addition of sulfuric acid, magnesium chloride solution and heat. The hydrogen cyanide gas is trapped in a scrubber containing sodium hydroxide solution. The color is formed when the reagents of chloramine-T and pyridine-barbifuric acid mixture is added into scrubber solution. The intensity of the color is measured spectrophotometrically and is proportional to the concentration of cyanide in the solution.

#### SDG NARRATIVE

Accredited Labs received 9 soil samples (Project: LAKA RI; ALI Case #8050) from LMS Engineers on 01/12/98 for the analyses of Volatile Organics, TAL Metals and Total Cyanide.

All analyses were performed within the required holding time.

All soil analyses were reported on a dry weight basis.

"I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed Release of the data contained in this hardcopy data package has been authorized by the Laboratory Manager or his designee, as verified by the following signature."

FORM: 291COC

#### METHODOLOGY SUMMARY

Volatile Organics: EPA-CLP-SOW (Document Number OLM03.1)

#### Soil/Sediment Samples

a. Low level:

An inert gas is purged through a mixture containing 5g of sample and reagent water at an elevated temperature. The volatile organics are efficiently transferred from aqueous phase to the vapor phase and then trapped onto a sorbent column. When purging is completed, the sorbent column is heated and backflushed with the inert gas to desorb the volatile organics from the sorbent column to a GC column. The GC is temperature programmed to separate the volatile organics which are then detected and quantified with a mass spectrometer.

TAL Metals: EPA-CLP-SOW (Document Number ILM04.0)

#### Soil/Sediment Samples

A 1qm portion of sample is digested with nitric acid and hydrogen The digestate is then refluxed with either nitric acid or hydrochloric acid. Diluted hydrochloric acid is used as the final reflux acid for the Furnace AA analysis of Sb, the Flame AA or ICP analysis of Al, Sb, Ba, Be, Ca, Cd, Cr, Co, Cu, Fe, Pb, Mq, Mn, Ni, K, Ag, Na, Tl, V and Zn. Nitric acid is employed as the final reflux acid for the Furnace AA analysis of As, Be, Cd, Cr, Co, Cu, Fe, Pb, Mn, Ni, Se, Ag, Tl, V and Zn. For the graphite furnace analysis, an aliquot of the digestate is spiked with modifier solution and is placed into the graphite furnace. aliquot is then slowly evaporated to dryness, charred and atomized. The absorption of the EDL radiation during atomization is proportional to the element concentration. For the flame AA, the digestate is aspirated and atomized in a flame. The absorption of the HCL radiation during atomization is proportional to the element concentration. The basis of ICAP method is the measurement of atomic emission by an optical spectroscope technique. spectra are dispersed by a grating spectrometer and the intensities of the line are measured and processed by a computer system. mercury analysis, a 0.2gm portion of sample is digested with potassium permanganate and persulfate at acidic condition in a water bath at 95°C. The mercury in the sample is reduced to the elemental state and detected by the cold vapor technique in a closed system.

Total Cyanide: EPA-CLP-SOW (Document Number ILM03.0)

#### Soil/Sediment Samples

23

A 1-5gm portion of sample mixed with reagent water is placed into a cyanide distillation appartus. Hydrogen cyanide gas is liberated from the aqueous solution upon addition of sulfuric acid, magnesium chloride solution and heat. The hydrogen cyanide gas is trapped in a scrubber containing sodium hydroxide solution. The color is formed when the reagents of chloramine-T and pyridine-barbifuric

acid mixture is added into scrubber solution. The intensity of the color is measured spectrophotometrically and is proportional to the concentration of cyanide in the solution.

#### SDG NARRATIVE

Accredited Labs received 17 soil samples (Project: LAKA RI (650-272); ALI Case #8069) from LMS Engineers on 01/13/98 for the analyses of Volatile Organics, TAL Metals and Total Cyanide.

All analyses were performed within the required holding time.

All soil analyses were reported on a dry weight basis.

"I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed Release of the data contained in this hardcopy data package has been authorized by the Laboratory Manager or his designee, as verified by the following signature."

Yun-shen Lee,

Technical Director

ACCREDITED LABORATORIES, INC.

#### METHODOLOGY SUMMARY

Volatile Organics: EPA-CLP-SOW (Document Number OLM03.1)

### Soil/Sediment Samples

#### a. Low level:

An inert gas is purged through a mixture containing 5g of sample and reagent water at an elevated temperature. The volatile organics are efficiently transferred from aqueous phase to the vapor phase and then trapped onto a sorbent column. When purging is completed, the sorbent column is heated and backflushed with the inert gas to desorb the volatile organics from the sorbent column to a GC column. The GC is temperature programmed to separate the volatile organics which are then detected and quantified with a mass spectrometer.

TAL Metals: EPA-CLP-SOW (Document Number ILM04.0)

### Soil/Sediment_Samples

A 1qm portion of sample is digested with nitric acid and hydrogen peroxide. The digestate is then refluxed with either nitric acid or hydrochloric acid. Diluted hydrochloric acid is used as the final reflux acid for the Furnace AA analysis of Sb, the Flame AA or ICP analysis of Al, Sb, Ba, Be, Ca, Cd, Cr, Co, Cu, Fe, Pb, Mg, Mn, Ni, K, Ag, Na, Tl, V and Zn. Nitric acid is employed as the final reflux acid for the Furnace AA analysis of As, Be, Cd, Cr, Co, Cu, Fe, Pb, Mn, Ni, Se, Ag, Tl, V and Zn. For the graphite furnace analysis, an aliquot of the digestate is spiked with modifier solution and is placed into the graphite furnace. aliquot is then slowly evaporated to dryness, charred and atomized. The absorption of the EDL radiation during atomization is proportional to the element concentration. For the flame AA, the digestate is aspirated and atomized in a flame. The absorption of the HCL radiation during atomization is proportional to the element concentration. The basis of ICAP method is the measurement of atomic emission by an optical spectroscope technique. The emission spectra are dispersed by a grating spectrometer and the intensities of the line are measured and processed by a computer system. mercury analysis, a 0.2gm portion of sample is digested with potassium permanganate and persulfate at acidic condition in a water bath at 95°C. The mercury in the sample is reduced to the elemental state and detected by the cold vapor technique in a closed system.

Total Cyanide: EPA-CLP-SOW (Document Number ILM03.0)

### Soil/Sediment_Samples

A 1-5gm portion of sample mixed with reagent water is placed into a cyanide distillation appartus. Hydrogen cyanide gas is liberated from the aqueous solution upon addition of sulfuric acid, magnesium chloride solution and heat. The hydrogen cyanide gas is trapped in a scrubber containing sodium hydroxide solution. The color is formed when the reagents of chloramine-T and pyridine-barbifuric

acid mixture is added into scrubber solution. The intensity of the color is measured spectrophotometrically and is proportional to the concentration of cyanide in the solution.
